SRAM 컨트롤러(스크램블)

What this is. An SRAM controller that scrambles addresses and data and adds ECC.

Why it exists. Because secrets in memory can be read physically. Decapsulating a die and probing SRAM cells is a practised attack, so contents are scrambled; independently, soft errors require ECC.

Undergraduate review · EECS concepts. Lightweight block ciphers (PRINCE and similar); SECDED Hamming codes; soft-error rate and FIT units.

Graduate · Practice note. ECC adds a cycle of latency. Confirm early that the pipeline can absorb it; discovering this after timing closure forces a redesign.

OTP 컨트롤러

What this is. A controller for one-time-programmable memory.

Why it exists. Because some state must be unerasable: device-unique keys, life-cycle state, trim values. Since writes are irreversible, the programming procedure is extremely conservative.

Undergraduate review · EECS concepts. Non-volatile memory physics (eFuse, antifuse); error correction; idempotent writes.

Graduate · Practice note. A defect here produces permanently unusable devices. Verify this block more conservatively than any other.

키 관리자

What this is. Derives purpose-specific keys from a root key and gates access by life-cycle state.

Why it exists. To keep key material out of software entirely. Software requests an operation with a named key; the value travels only over hardware paths to the crypto engines.

Undergraduate review · EECS concepts. Key derivation functions; chain of trust; least privilege; hardware isolation.

Graduate · Practice note. Whether the hardware key path is genuinely isolated can only be established by reading the RTL: debug paths, scan chains and test modes are the usual leaks. **A scan chain can read every flip-flop**, which is why production parts lock scan.

수명주기 컨트롤러

What this is. Manages life-cycle state (RAW → TEST → DEV → PROD → RMA) and gates features accordingly.

Why it exists. Because some capabilities must exist in the factory and not in the field — test modes, debug, key injection. Transitions are irreversible and authenticated by tokens.

Undergraduate review · EECS concepts. State machines; access control; irreversible transitions; fail-closed defaults.

Graduate · Practice note. This block encodes product strategy in silicon. Which features are locked and when is a business decision, which makes it the block whose requirements change most often.

What this is. The flash controller's interface logic.

Why it exists. Because embedded flash holds the code that runs before anything else. Its controller therefore participates in secure boot: it must enforce read/write/erase permissions per region and cooperate with the life-cycle state.

Undergraduate review · EECS concepts. Non-volatile memory programming; wear levelling; region-based access control; integrity checking of stored code.

Graduate · Practice note. Flash operations are slow and blocking relative to the CPU, so the controller's interface must allow the core to make progress. The resulting concurrency — erase in progress while reads continue from another bank — is where the verification effort concentrates.

OpenTitan 기본 셀 라이브러리

What this is. Synchronisers, FIFOs, counters, LFSRs, arbiters, parity and ECC helpers, and security primitives such as duplicated registers and complementary signal pairs.

Why it exists. To get the subtle things right once. A synchroniser written independently in every block will be wrong in at least one of them; written once and verified once, it is correct everywhere.

Undergraduate review · EECS concepts. Metastability and MTBF; Gray coding; LFSRs and primitive polynomials; arbitration fairness.

Graduate · Practice note. This library is the first thing a one-person IP house should build. A block cannot be sold unless the primitives inside it are already trusted. OpenTitan's `prim_` modules are Apache-2.0 licensed and are a sound starting point.

4 //
5 // The alert receiver primitive decodes alerts that have been
  differentially
6 // encoded and transmitted via a handshake protocol on
  alert_p/n and
7 // ack_p/n. In case an alert handshake is initiated, the out-
  put alert_o will
8 // immediately be asserted (even before completion of the
  handshake).
9 //
10 // In case the differential input is not correctly encoded,
  this module will
11 // raise an error by asserting integ_fail_o.
12 //
13 // Further, the module supports ping testing of the alert diff
  pair. In order to
14 // initiate a ping test, ping_req_i shall be set to 1'b1 until
  ping_ok_o is
15 // asserted for one cycle. The signal may be de-asserted (e.g.
  after a long)
16 // timeout period. However note that all ping responses that
  come in after
17 // deasserting ping_req_i will be treated as native alerts.
18 //
19 // The protocol works in both asynchronous and synchronous
  cases. In the
20 // asynchronous case, the parameter AsyncOn must be set to
  1'b1 in order to
21 // instantiate additional synchronization logic. Further, it
  must be ensured
22 // that the timing skew between all diff pairs is smaller than
  the shortest
23 // clock period of the involved clocks.
24 //
25 // Note that in case of synchronous operation, alerts on the
  diffpair are
26 // decoded combinatorially and forwarded on alert_o within the
  same cycle.
27 //
28 // See also: prim_alert_sender, prim_diff_decode,
  alert_handler

4 //
5 // The alert sender primitive module differentially encodes
and transmits an
6 // alert signal to the prim_alert_receiver module. An alert
will be signalled
7 // by a full handshake on alert_p/n and ack_p/n. The
alert_req_i signal may
8 // be continuously asserted, in which case the alert sig-
nalling handshake
9 // will be repeatedly initiated.
10 //
11 // The alert_req_i signal may also be used as part of req/ack.
The parent module
12 // can keep alert_req_i asserted until it has been ack'd
(transferred to the alert
13 // receiver). The parent module is not required to use this.
14 //
15 // In case the alert sender parameter IsFatal is set to 1, an
incoming alert
16 // alert_req_i is latched in a local register until the next
reset, causing the
17 // alert sender to behave as if alert_req_i were continuously
asserted.
18 // The alert_state_o output reflects the state of this intern-
al latching register.
19 //
20 // The alert sender also exposes an alert test input, which
can be used to trigger
21 // single alert handshakes. This input behaves exactly the
same way as the
22 // alert_req_i input with IsFatal set to 0. Test alerts do not
cause alert_ack_o
23 // to be asserted, nor are they latched until reset (regard-
less of the value of the
24 // IsFatal parameter).
25 //
26 // Further, this module supports in-band ping testing, which
means that a level
27 // change on the ping_p/n diff pair will result in a full-
handshake response
28 // on alert_p/n and ack_p/n.
29 //
30 // The protocol works in both asynchronous and synchronous
cases. In the
31 // asynchronous case, the parameter AsyncOn must be set to
1'b1 in order to
32 // instantiate additional synchronization logic. Further, it
must be ensured
33 // that the timing skew between all diff pairs is smaller than
the shortest
34 // clock period of the involved clocks.
35 //
36 // Incorrectly encoded diff inputs can be detected and will be
signalled
37 // to the receiver by placing an inconsistent diff value on
the differential
38 // output (and continuously toggling it).
39 //

5 // prim_alert_to_diff: This module receives an alert signal
  (using the alert protocol) and
6 // translates it into a differentially encoded signal (without the
  alert protocol).
7 // It also handles integrity errors from the alert receiver,
  treating them as alerts.
8 //
9 // IMPORTANT: This primitive is NOT intended to be used in
  OpenTitan top-level designs.
10 // In top-level designs, prim_alert_{sender,receiver} pairs
  should be used instead.
11 // The intended use case of this primitive is to signal an
  alert through a differential
12 // encoding (for minimal integrity protection) to modules that do
  not support
13 // OpenTitan's alert protocol.

13 //
14 // This is a tree implementation of a round robin arbiter. It
15 has the same behavior as the PPC
16 // implementation in prim_arbiter_ppc, and also uses a prefix
17 summing approach to determine the next
18 // request to be granted. The main difference with respect to
19 the PPC arbiter is that the leading 1
20 // detection and the prefix summation are performed with a
21 binary tree instead of a sequential loop.
22 // Also, if the data port is enabled, the data is muxed based
23 on the local arbitration decisions at
24
25 // each node of the arbiter tree. This means that the data can
26 propagate through the tree
27 // simultaneously with the requests, instead of waiting for
28 the arbitration to determine the winner
29 // index first. As a result, this design has a shorter critic-
30 al path than other implementations,
31 // leading to better overall timing.
32
33 // Note that the currently winning request is held if the data
34 sink is not ready. This behavior is
35 // required by some interconnect protocols (AXI, TL). The mod-
36 ule contains an assertion that checks

5 // This is a wrapper module that instantiates two prim_arbit-
er_tree modules.
6 // The reason for two is similar to modules such as
prim_count/prim_lfsr where
7 // we use spatial redundancy to ensure the arbitration results are
not altered.
8 //
9 // Note there are limits to this check, as the inputs to the
duplicated arbiter
10 // is still a single lane. So an upstream attack can defeat
this module. The
11 // duplication merely protects against attacks directly on the
arbiter.

59
60 // The basic helper macros are actually defined in "implement-
ation headers". The macros should do
61
62 // the same thing in each case (except for the dummy flavour),
but in a way that the respective
63 // tools support.
64 //
65 // If the tool supports assertions in some form, we also
define INC_ASSERT (which can be used to
66 // hide signal definitions that are only used for assertions).
67 //
68 // The list of basic macros supported is:
69 //
70 // ASSERT_I: Immediate assertion. Note that immediate as-
sertions are sensitive to simulation
71 // glitches.
72 //
73 // ASSERT_INIT: Assertion in initial block. Can be used for
things like parameter checking.
74 //
75 // ASSERT_INIT_NET: Assertion in initial block. Can be used
for initial value of a net.
76 //
77 // ASSERT_FINAL: Assertion in final block. Can be used for
things like queues being empty at end of
78 // sim, all credits returned at end of sim,
state machines in idle at end of sim.

```

```

73 //
74 // ASSERT_AT_RESET: Assertion just before reset. Can be used
to check sum-like properties that get
75 // cleared at reset.
76 // Note that unless your simulation ends
with a reset, the property does not get
77 // checked at end of simulation; use AS-
SERT_AT_RESET_AND_FINAL if the property
78 // should also get checked at end of simula-
tion.
79 //

80 // ASSERT_AT_RESET_AND_FINAL: Assertion just before reset and in
final block. Can be used to check
81 // sum-like properties before
every reset and at the end of simulation.
82 //
83 // ASSERT: Assert a concurrent property directly. It
can be called as a module (or
84 // interface) body item.
85 //
86 // Note: We use (__rst != '0') in the disable
iff statements instead of (__rst ==

87 // '1). This properly disables the assertion in
cases when reset is X at the
88 // beginning of a simulation. For that case,
(reset == '1) does not disable the
89 // assertion.
90 //
91 // ASSERT_NEVER: Assert a concurrent property NEVER happens
92 //
93 // ASSERT_KNOWN: Assert that signal has a known value (each
bit is either '0' or '1') after reset.
94 // It can be called as a module (or interface)
body item.
95 //
96 // COVER: Cover a concurrent property
97 //
98 // ASSUME: Assume a concurrent property
99 //
100 // ASSUME_I: Assume an immediate property
101 //

5 // This module should be instantiated within flops of CDC syn-
  chronization primitives,
6 // and allows DV to model real CDC delays within simulations,
  especially useful at the chip level
7 // or in IPs that communicate across clock domains.
8 //
9 // The instrumentation is very simple: when this is enabled
  the input into the first
10 // synchronizer flop has a mux where the select is randomly
  set. One of the mux inputs is the input
11 // of this module, and the other is the output of the first
  flop: selecting the latter models the
12 // effect of the first flop missing the input transition.
13 //
14 // Notice the delay should cause the input to be skipped by at
  most a single cycle. As a perhaps
15 // unnecessary precaution, the select will only be allowed to
  be random when the input changes.

5 // Hardened counter primitive:
6 //
7 // This internally uses a cross counter scheme with primary
and a secondary counter, where the
8 // secondary counter counts in reverse direction. The sum of
both counters must remain constant and
9 // equal to 2**Width-1 or otherwise an err_o will be asserted.
10 //
11 // This counter supports a generic clear / set / increment /
decrement interface:
12 //
13 // clr_i: This clears the primary counter to ResetValue and
adjusts the secondary counter to match
14 // (i.e. 2**Width-1-ResetValue). Clear has priority
over set, increment and decrement.
15 // set_i: This sets the primary counter to set_cnt_i and ad-
justs the secondary counter to match
16 // (i.e. 2**Width-1-set_cnt_i). Set has priority over
increment and decrement.
17 // incr_en_i: Increments the primary counter by step_i, and
decrements the secondary by step_i.
18 // decr_en_i: Decrements the primary counter by step_i, and
increments the secondary by step_i.
19 // commit_i: Counter changes only take effect when `commit_i`
is set. This does not effect the
20 // `cnt_after_commit_o` output which gives the next
counter state if the change is
21 // committed.
22 //
23 // Note that if both incr_en_i and decr_en_i are asserted at
the same time, the counter remains
24 // unchanged. The counter is also protected against under- and
overflows.

6 //
7 // This module takes in n-bits data words (n defined by Byte-
PerWord parameter) and updates an
8 // internally stored CRC with each valid data word. The poly-
nomial used is the standard CRC32 IEEE
9 // one. An interface is provided to set the internal CRC to an ar-
bitrary value. The output CRC is an
10 // inverted version of the internally stored CRC and the input
CRC is inverted before being stored.
11 // This is done so results match existing widely used software
libraries (e.g. the crc32
12 // functionality available in Python). Note that a initial CRC of
0x0 (corresponding to an internal
13 // CRC of 0xffffffff) must be used to match results generated
elsewhere.

5 // This module decodes a differentially encoded signal and de-
fects
6 // incorrectly encoded differential states.
7 //
8 // In case the differential pair crosses an asynchronous
boundary, it has
9 // to be re-synchronized to the local clock. This can be
achieved by
10 // setting the AsyncOn parameter to 1'b1. In that case, two
additional
11 // input registers are added (to counteract metastability),
and
12 // a pattern detector is instantiated that detects skewed
level changes on
13 // the differential pair (i.e., when level changes on the diff
pair are
14 // sampled one cycle apart due to a timing skew between the
two wires).
15 //
16 // See also: prim_alert_sender, prim_alert_receiver,
alert_handler

Caliptra SHA-512

What this is. SHA-512 from a datacentre root-of-trust design.

Why it exists. Because measurement of firmware needs a collision-resistant digest, and SHA-512 is the width used for attestation in that ecosystem.

Undergraduate review · EECS concepts. Hash construction; 64-bit datapath arithmetic; message scheduling.

Graduate · Practice note. Compare the round structure with the SHA-256 core: the same algorithmic shape at double width shows how word width propagates through a design.

Caliptra SHA-256

What this is. SHA-256 in a root-of-trust context.

Why it exists. Because the boot measurement chain requires it and a root of trust cannot rely on software for its own integrity check.

Undergraduate review · EECS concepts. Hash functions; boot-time measurement; chain of trust.

Graduate · Practice note. A root of trust is interesting less for its algorithms than for its *ordering* guarantees: what is measured before what, and what cannot be changed afterwards.

Caliptra HMAC

What this is. Keyed-hash message authentication in a root of trust.

Why it exists. Because integrity without authentication is insufficient: a plain digest can be recomputed by an attacker who can modify the data.

Undergraduate review · EECS concepts. HMAC construction; key handling; constant-time comparison.

Graduate · Practice note. Compare digests in constant time. A byte-by-byte comparison that returns early leaks the position of the first difference through timing — a classic and easily fixed vulnerability.

Caliptra ECC (P-384)

What this is. Elliptic-curve arithmetic over the NIST P-384 curve.

Why it exists. Because attestation requires digital signatures, and ECC provides them at far smaller key sizes than RSA for equivalent classical security.

Undergraduate review · EECS concepts. Elliptic curve group law; modular arithmetic; Montgomery ladder for constant-time scalar multiplication; projective coordinates to avoid inversions.

Graduate · Practice note. Scalar multiplication must be constant time and regular: any dependence of the operation sequence on secret scalar bits leaks the key. The Montgomery ladder exists for this reason, not for speed.

17 // ecc_dsa_ctrl.sv
18 // -----
19 // Elliptic Curve Cryptography (ECC) digital signature al-
gorithm (DSA)
20 // controller to support deterministic ECDSA based on RFC
6979.
21 // The dsa architecture includes several countermeasures to
be protected
22 // against a subset of side-channel analysis (SCA) attacks.
23 //
24 // The architecture includes:
25 // 1) ecc_dsa_sequencer: including the required sequence to
perform
26 //    keygen, signing, and verifying.
27 // 2) ecc_arith_unit: the arithmetic unit to perform point
multiplication
28 //    and other required operations
29 // 3) hmac_drbg: the hmac384 drbg component to support RFC
6979
30 // 4) ecc_scalar_blinding: the SCA countermeasure to random-
ized scalar
31 //    to avoid information leakage.
32 //
33 // The embedded countermeasures are:
34 // - point randomization:
35 //
36 // Randomized Projective Coordinates countermeasure based on
section 5.3
37 //
38 // "Resistance against Differential Power Analysis for
Elliptic Curve
39 // Cryptosystems" in CHES 1999 by Coron, J.
40 // This countermeasure uses a random value "lambda" in
point multiplication
41 // (Q = k * P) in keygen/signing to randomize base point
P = (X, Y, 1)
42 // as follows:
43 // P = (X * Lambda, Y * lambda, Lambda)
44 // - scalar blinding:
45 // Scalar blinding countermeasure based on section 5.1
46 // "Resistance against Differential Power Analysis for
Elliptic Curve
47 // Cryptosystems" in CHES 1999 by Coron, J.
48 // This countermeasure uses a random value "r" in the
point multiplication
49 // (Q = k * P) in keygen/signing to randomize scalar k as
follows:
50 // k = k + r*group_order
51 // - masking signature:
52 //
53 // Masking sign countermeasure uses a random value "d" in
the signing
54 //
55 // operation to generate signature proof s = (privkey * r +
h)*k_inv
56 // as follows:
57 // s = (((privkey - d) * r + (h - d)) * k_inv) + [(d * r
+ d) * k_inv]

17 // ecc_dsa_sequencer.sv
18 // -----
19 // This module contains the sequence of ECC operation. it in-
cludes 4 sequences
20 // of operation:
21 // 1) reset sequence: After reset, the core will initilze the
data memory based
22 // on the first lines of sequencer. Then,
it will stay on NOP
23 // line until getting the command.
24 // 2) keygen sequence: After getting the keygen command, it
will generate and
25 // randomize privkey and feed it into the
pm core and return
26 // key pairs of (privkey, pubkey)
27 // 3) sign sequence: After getting the sign command, it will
generate and
28 // randomize nonce and feed it into the pm
core and return
29 // the signature (R,
S).
30 // 4) verify sequence: After getting the verify command, it
will feed the signature
31 // into the pm core and return the com-
puted verify_R.
32 //
33 //

19 // interface with hmac_drbg component to generate the required
20 // values:
21 // 1) in keygen mode:
22 // 1.1. generate lambda from IV for point randomization
23 // SCA countermeasure
24 // 1.2. generate scalar_rnd from IV for scalar blinding
25 // SCA countermeasure
26 // 1.3. generate privkey from seed and nonce for key gen-
27 // eration
28 // 2) in sign mode:
29 // 2.1. generate lambda from IV for point randomization
30 // SCA countermeasure
31 // 2.2. generate scalar_rnd from IV for scalar blinding
32 // SCA countermeasure
33 // 2.3. generate masking_rnd from IV for masking signa-
34 // ture SCA countermeasure
35 // 2.4. generate k from privkey and hashed_msg for sign-
36 // ing
37 //
38 // To generate random values using IV, the hmac_drbg is con-
39 // tinued by triggering
40 // next command (instead of init).
41 //
42 // - INIT: Instantiates HMAC-DRBG with entropy,
43 // nonce, (personalization string is empty).
44 // Then, it calls
45 // HMAC_DRBG_Generate_algorithm (additional input string is empty)
46 // to generate a 384-bit random value while
47 // it's in (0, prime) range.
48 // if the random value is zero or >= prime,
49 // it is rejected and a new random value
50 // is generated by calling
51 // HMAC_DRBG_Generate_algorithm.
52 // There is NO RESEED process.
53 // - NEXT: it calls HMAC_DRBG_Generate_algorithm (ad-
54 // ditional input string is empty)
55 // to generate a 384-bit random value while
56 // it's in (0, prime) range.
57 // if the random value is zero or >= prime,
58 // it is rejected and a new random value
59 // is generated by calling

16 // Module:
17 // ecc_montgomerymultiplier.sv
18 //
19 // Montgomery Multiplier based on
20 // Optimized Algorithms and Architectures for Montgomery Mul-
tiplication
21 // for Post-quantum Cryptography by Rami Elkhatab et. al.
22 //
23 // Description:
24 // The module produces a Montgomery product of input op-
erands with the following constraints:
25 //
26 // Input operands must be less than n_i, i.e. opa_i <
n_i and opb_i < n_i.
27 //
28 // RADIX > 2
29 //
30 // R = 2^((ceil($bits(n_i) / RADIX) + 1) * RADIX)
31 //
32 // R > n_i.
33 //
34 // (1) T = opa_i * opb_i < n_i * n_i = n_i^2
35 //
36 // (2) p_internal = (T + (T*n_prime mod R) * n_i) / R
37 //
38 // (3) p_subtracted_internal = p_internal - n_i
39 //
40 // (4) p_o = (p_internal >= ni)? p_subtracted_internal :
p_internal
41 //
42 // From (1) and (2) given R > n_i, and opa_i, opb_i <
n_i:
43 //
44 // p_internal < (n_i^2 + R * n_i) / R = n_i + n_i^2 / R
45 //
46 // < n_i + n_i^2 / n_i = n_i + n_i = 2*n_i
47 //
48 // From (3) and (4):
49 //
50 // p_subtracted_internal < 2*n_i - n_i = n_i
51 //
52 // p_o < n_i
53 //

18 // -----
19 // ECC point multiplication controller for the Secp384.
20 //
21 // The architecture includes ecc_pm_sequencer including the
22 // sequence to perform:
23 // - point multiplication (pm) based on Montgomery ladder
24 // and Fermat's little
25 // theorem (FLT) inversion
26 // - Montgomery ladder initialization with base point G or
27 // public key PK in
28 // keygen, signing, or verifying operations.
29 // - Montgomery ladder steps: including the iterative point
30 // addition (PA)
31 //
32 // and point doubling (PD) operations in Montgomery domain
33 // using projective
34 // coordinates. The number of iteration is equal to REG_S-
35 // IZE of scalar in
36 //
37 // unprotected point multiplication, and REG_SIZE+RND_SIZE of
38 // scalar in the
39 //
40 // SCA protected operation.
41 // - Modular Inversion (mod p, mod q) is based on Fermat's
42 // little theorem (FLT)
43 // inversion.
44 // - Conversion from projective coordinates in Montgomery
45 // domain (X,Y,Z) to
46 // affine coordinates in the normal domain (x,y).
47 // - Modular arithmetic operations such as (h + r*privKey)
48 // in signing
49 // or (h*s_inv) and (r*s_inv) in verifying
50 //

Caliptra AES

What this is. AES within a datacentre root of trust.

Why it exists. Because confidentiality is required alongside integrity, and a root of trust must provide both without exporting keys.

Undergraduate review · EECS concepts. Block cipher modes; key hierarchies; hardware key paths.

Graduate · Practice note. Compare this implementation's countermeasure set with OpenTitan's. Different threat models — a datacentre module versus a device exposed to physical attack — produce different designs from the same standard.

387
388 // SEC_CM: CTRL.SPARSE
389 // We use sparse encodings for various critical signals and
must ensure that:
390 // 1. The synthesis tool doesn't optimize away the sparse
encoding.
391 // 2. The sparsely encoded signal is always valid. More pre-
cisely, an alert or SVA is triggered
392 // 3. The alert signal remains asserted until reset even if
the sparse signal becomes valid again
393 // This is achieved by driving the control FSM into the
terminal error state whenever any
394 // sparsely encoded signal becomes invalid.
395 // If any sparsely encoded signal becomes invalid, the
cipher core further immediately de-asserts
396 // the out_valid_o signal to prevent any data from being re-
leased.

5 // AES cipher core control FSM
6 //
7 // This module contains the AES cipher core control FSM oper-
ating on and producing the negated
8 // values of important control signals. This is achieved by:
9 // - instantiating the regular AES cipher core control FSM op-
erating on and producing the positive
10 // values of these signals, and
11 // - inverting these signals between the regular FSM and the
caliptra_prim_buf synthesis barriers.
12 // Synthesis tools will then push the inverters into the actu-
al FSM.

7 // This module contains the AES cipher core including, state
register, full key and decryption key
8 // registers as well as key expand module and control unit.
9 //
10 //
11 // Masking
12 // -----
13 //
14 // If the parameter "Masking" is set to one, first-order mask-
ing is applied to the entire
15 // cipher core including key expand module. For details, see
Rivain et al., "Provably secure
16 // higher-order masking of AES" available at https://
eprint.iacr.org/2010/441.pdf .
17 //
18 //
19 // Details on the data formats
20 // -----
21 //
22 // This implementation uses 4-dimensional SystemVerilog arrays to
represent the AES state:

```

```

23 //
24 // logic [3:0][3:0][7:0] state_q [NumShares];
25 //
26 // The fourth dimension (unpacked) corresponds to the differ-
ent shares. The first element holds the
27 // (masked) data share whereas the other elements hold the
masks (masked implementation only).

28 // The three packed dimensions correspond to the 128-bit state
matrix per share. This
29 // implementation uses the same encoding as the Advanced En-
cryption Standard (AES) FIPS Publication
30 // 197 available at https://www.nist.gov/publications/ad-
vanced-encryption-standard-aes (see Section
31 // 3.4). An input sequence of 16 bytes (128-bit, left most
byte is the first one)
32 //
33 // b0 b1 b2 b3 b4 b5 b6 b7 b8 b9 b10 b11 b12 b13 b14 b15
34 //
35 // is mapped to the state matrix as
36 //
37 // [ b0 b4 b8 b12 ]
38 // [ b1 b5 b9 b13 ]
39 // [ b2 b6 b10 b14 ]
40 // [ b3 b7 b11 b15 ] .
41 //
42 // This is mapped to three packed dimensions of SystemVerilog
array as follows:
43 // - The first dimension corresponds to the rows. Thus,
state_q[0] gives
44 // - The first row of the state matrix [ b0 b4 b8
b12 ], or
45 // - A 32-bit packed SystemVerilog array 32h'{ b12, b8, b4,
b0 }.
46 //
47 // - The second dimension corresponds to the columns. To ac-
cess complete columns, the state matrix
48 // must be transposed first. Thus state_transposed =
aes_pkg::aes_transpose(state_q) and then
49 // state_transposed[1] gives
50 // - The second column of the state matrix [ b4 b5 b6
b7 ], or
51 // - A 32-bit packed SystemVerilog array 32h'{ b7, b6, b5,
b4 }.
52 //
53 // - The third dimension corresponds to the bytes.
54 //
55 // Note that the CSRs are little-endian. The input sequence
above is provided to 32-bit DATA_IN_0 -
56 // DATA_IN_3 registers as
57 //
58 // - DATA_IN_0 32h'{ b3 , b2 , b1 , b0 }
59 // - DATA_IN_1 32h'{ b7 , b6 , b4 , b4 }
60 // - DATA_IN_2 32h'{ b11, b10, b9 , b8 }
61 // - DATA_IN_3 32h'{ b15, b14, b13, b12 } .
62 //
63 // The input state can thus be obtained by transposing the
content of the DATA_IN_0 - DATA_IN_3
64 // registers.
65 //

66 // Similarly, the implementation uses a 3-dimensional array to
represent the AES keys:
67 //
68 // logic [7:0][31:0] key_full_q [NumShares]
69 //

70 // The third dimension (unpacked) corresponds to the different
shares. The first element holds the
71 // (masked) key share whereas the other elements hold the
masks (masked implementation only).

72 // The two packed dimensions correspond to the 256-bit key per
share. This implementation uses
73 // the same encoding as the Advanced Encryption Standard (AES)
FIPS Publication
74 // 197 available at https://www.nist.gov/publications/ad-
vanced-encryption-standard-aes .
75 //
76 // The first packed dimension corresponds to the 8 key words.
The second packed dimension
77 // corresponds to the 32 bits per key word. A key sequence of
32 bytes (256-bit, left most byte is
78 // the first one)
79 //
80 // b0 b1 b2 b3 b4 b5 b6 b7 b8 b9 b10 b11 b12 b13 b14
b15 ... b28 b29 b30 b31
81 //
82 // is mapped to the key words and registers (little-endian) as
83 //
84 // - KEY_SHARE0_0 32h'{ b3 , b2 , b1 , b0 }
85 // - KEY_SHARE0_1 32h'{ b7 , b6 , b4 , b4 }
86 // - KEY_SHARE0_2 32h'{ b11, b10, b9 , b8 }
87 // - KEY_SHARE0_3 32h'{ b15, b14, b13, b12 }
88 // - KEY_SHARE0_4 32h'{ . . . . }
89 // - KEY_SHARE0_5 32h'{ . . . . }
90 // - KEY_SHARE0_6 32h'{ . . . . }
91 // - KEY_SHARE0_7 32h'{ b31, b30, b29, b28 } .
92 //

347
348     // Extract randomness for masking the input data.
349     //
350     // The masking PRNG is used for generating both the PRD for
the S-Boxes/SubBytes operation as
351     // well as for the input data masks. When using any of the
masked Canright S-Box implementations,
352     // it is important that the SubBytes input masks (generated
by the PRNG in Round X-1) and the
353     // SubBytes output masks (generated by the PRNG in Round X)
are independent. This can be achieved
354     // by using e.g. an unrolled Bivium stream cipher primitive
inside the PRNG. Since the input data
355     // masks become the SubBytes input masks in the first round,
we select the same 8 bit lanes for
356     // the input data masks which are also used to form the Sub-
Bytes output mask for the masked
357     // Canright S-Box implementations, i.e., the 8 LSBs of the
per S-Box PRD. In particular, we have:

```

```

358 //
359 // prd_masking = { prd_key_expand, ... , sb_prd[4],
sb_out_mask[4], sb_prd[0], sb_out_mask[0] }
360 //
361 // Where sb_out_mask[x] contains the SubBytes output mask
for byte x (when using a masked
362 // Canright S-Box implementation) and sb_prd[x] contains ad-
ditional PRD consumed by SubBytes for
363 // byte x.
364 //
365 // When using a masked S-Box implementation other than Can-
right, we still select the 8 LSBs of
366 // the per-S-Box PRD to form the input data mask of the cor-
responding byte. We do this to
367 // distribute the input data masks over all output bits the
masking PRNG. We do the extraction on
368 // a row basis.

PULP 기본 셀 (FIFO·CDC·아비터)

What this is. The PULP platform's common cells: FIFOs, two-phase and Gray-coded CDC, round-robin arbiter trees, stream registers and spill registers.

Why it exists. Because every SoC needs them and getting them wrong is expensive. The spill register in particular exists to break the combinational valid/ready loop that appears whenever two modules are connected directly.

Undergraduate review · EECS concepts. Metastability; Gray coding; handshake protocols; arbitration; pipeline decoupling.

Graduate · Practice note. Read `cc_spill_register.sv` closely. It solves a problem — the zero-delay handshake cycle — that is invisible when each module is tested alone and appears immediately on integration.

14 // Author: Wolfgang Roenninger <wroennin@ethz.ch>
15 //
16 // `cc_cb_filter`: This module implements a counting bloom
17 // filter with parameterizable hash functions.
18 //
19 // Functionality: A counting bloom filter is a data structure
20 // to efficiently implement
21 // set lookups. It does so by hashing its data
22 // inputs onto multiple pointers
23 // which serve as indicators for an array of
24 // buckets. For lookups can be
25 // false positives, but no false negatives.
26 // - Seeding: The pseudo random generators need seeds at
27 // elaboration time to generate
28 // different hashes. In principle any combina-
29 // tion of seeds can be used.
30 // But one should look that the hash outputs
31 // give sufficient different patterns,
32 // such that the resulting collision rate is
33 // low. The package `cc`
34 //
35 // contains the struct for seeding the PRG's in
36 // the hash functions.
37 // - Lookup:
38 // - Ports: `look_data_i`, `look_valid_o`
39 // - Description: Lookup combinational, `look_valid_o` is
40 // high, when `look_data_i` was
41 // previously put into the filter.
42 // - Increment:
43 // - Ports: `incr_data_i`, `incr_valid_i`
44 // - Description: Put data into the counting bloom filter,
45 // when valid is high.
46 // - Decrement:
47 // - Ports: `decr_data_i`, `decr_valid_i`
48 // - Description: Remove data from the counting bloom fil-
49 // ter. Only remove data that was
50 // previously put in, otherwise will go in a
51 // wrong state.
52 // - Status:
53 // - `clr_i`: Clears the filter and sets all coun-
54 // ters to 0.
55 //
56 // - `filter_usage_o`: How many data items are currently in
57 // the filter.
58 // - `filter_full_o`: Filter is full, can no longer hold
59 // more items.
60 // - `filter_empty_o`: Filter is empty.
61 // - `filter_error_o`: One of the internal counters or
62 // buckets overflowed.
63 //
64 // include "common_cells/assertions.svh"
65 //

14 /// A two-phase clock domain crossing.
15 ///
16 /// # Reset Behavior!!
17 ///
18 /// This module must not be used if warm reset capabilty is a
requirement. The
19 /// only exception is if you consistently use a reset control-
ler that sequences
20 /// the resets while gating both clock domains (be very care-
ful if you follow
21 /// this strategy!). If you need warm reset/clear/flush capab-
ilities, use (AND
22 /// CAREFULLY READ THE DESCRIPTION) the
cc_cdc_2phase_clearable module.
23 ///
24 /// After this disclaimer, here is how you connect the
src_rst_ni and the
25 /// dst_rst_ni of this module for power-on-reset (POR). The
src_rst_ni and
26 /// dst_rst_ni signal must be asserted SIMULTANEOUSLY (i.e.
asynchronous
27 /// assertion). Otherwise, spurious transactions could occur
in the domain
28 /// where the reset arrives later than the other. The de-as-
sertion of both reset
29 /// must be synchronized to their respective clock domain
(i.e. src_rst_ni must
30 /// be deasserted synchronously to the src_clk_i and
dst_rst_ni must be
31 /// deasserted synchronously to dst_clk_i.) You can use the
cc_rstgen cell in the
32 /// common_cells library to achieve this (synchronization of
only the
33 /// de-assertion). However, be careful about reset domain
crossings; If you
34 /// reset both domain asynchronously in their entirety (i.e.
POR) you are fine.
35 /// However, if you use this strategy for warm resets (some
parts of the circuit
36 /// are not reset) you might introduce metastability in this
separate
37 /// reset-domain when you assert the reset (the deassertion
synchronizer doesn't
38 /// help here).

17 // Description: Clearable Two-Phase CDC
18 // Transfer payloads with a two-phase handshake while coordin-
ating synchronous
19 // and optional asynchronous one-sided clears across source
and destination.
20
21 /// A two-phase clock domain crossing.
22 ///
23 /// CONSTRAINT: Requires max_delay of min_period(src_clk_i,
dst_clk_i) through
24 /// all asynchronous paths between the domains. The payload
CDC uses
25 /// async_payload_req, async_payload_ack, and
async_payload_data for the actual
26 /// data handshake. The clear sequencer CDCs use
async_reset_src2dst_req,
27 /// async_reset_dst2src_ack, async_reset_src2dst_next_phase,
28 /// async_reset_dst2src_req, async_reset_src2dst_ack, and
29 /// async_reset_dst2src_next_phase to handshake the clearing
state machines.
30 ///
31 ///
32 /// Reset Behavior:
33 ///
34 /// In contrast to the cc_cdc_2phase version without clear
signal, this module
35 /// supports one-sided warm resets (asynchronously and syn-
chronously). The way
36 /// this is implemented is described in more detail in the
cc_cdc_reset_ctrlr
37 /// module. To summarize a synchronous clear request i.e. src/

```

```

dst_clear_i will
38 /// cause the respective other clock domain to reset as well
without introducing
39 /// any spurious transactions. This is accomplished by an in-
ternal module
40 /// (cc_cdc_reset_ctrlr) that starts a reset sequence on both
sides of the CDC in
41 /// lock-step that first isolates the CDC from the outside
world and then resets
42 /// it. The reset sequencer provides the following behavior:
43 /// 1. There are no spurious invalid or duplicated transac-
tions regardless how
44 /// the individual sides are reset (can also happen roughly
simultaneously)
45 /// 2. The CDC becomes unready at the src side in the next
cycle after
46 /// synchronous reset request until the reset sequence is
completed. A currently
47 /// pending transactions might still complete (if the dst
accepts at the
48 /// exact time the reset is request on the src die).
49 /// 3. During the reset sequence the dst might withdraw the
valid signal. This
50 /// might violate higher level protocols. If you need this
feature you would
51 /// have to patch the existing implementation to wait with
the isolate_ack
52 /// assertion until all open handshakes were acknowledged.
53 /// 4. If the parameter ClearOnAsyncReset is enabled, the same
behavior as
54 /// above is also valid for asynchronous resets on either
side. However, this
55 /// increases the minimum number of synchronization stages
(SyncStages
56 /// parameter) from 2 to 3 (read the cc_cdc_reset_ctrlr
header to figure out
57 /// why).
58 ///

20 // Manuel Eggimann <meggimann@iis.ee.ethz.ch>
21 //
22 // A 4-phase clock domain crossing. While this is less effi-
23 // cient than a 2-phase
24 // CDC, it doesn't suffer from the same issues during one
25 // sided resets since
26 // the IDLE state doesn't alternate with every transaction.
27 //
28 // Parameters: data_t - The type of the data to transmit
29 // through the CDC.
30 //
31 // Decoupled - If decoupled is disabled, the 4phase cdc will
32 // not consume the
33 // src item until the handshake with the other side is com-
34 // pleted. This
35 // increases the latency of the first transaction but has no
36 // effect on
37 // throughput. However, critical paths might be slightly
38 // longer. Use this mode
39 // if you want to ensure that there are no in-flight transac-
40 // tions within the
41 // CDC.

```

```

26 //
27 // SendResetMsg - If send reset msg is enabled, the 4phase
28 // cdc starts sending
29 // the ResetMsg within its' asynchronous reset state. This
30 // can be usefull if
31 // we need to transmit a message to the other side of the CDC
32 // immediately
33 // during an async reset even if there is no clock available.
34 // This mode is
35 // required for proper functionality of the cc_cdc_re-
36 // set_ctrlr module.
37 //
38 // SyncStages - Number of synchronization stages for
39 // async_req and async_ack.
40 //
41 // CONSTRAINT: Requires max_delay of min_period(src_clk_i,
42 // dst_clk_i) through
43 // the paths async_req, async_ack, async_data.

17 /// A clock domain crossing FIFO, using 2-phase hand shakes.
18 ///
19 /// This FIFO has its push and pop ports in two separate clock
domains. Its size
20 /// can only be powers of two, which is why its depth is given as
2**LogDepth.
21 /// LogDepth must be at least 1.
22 ///
23 /// # Reset Behavior!!
24 ///
25 /// This module must not be used if warm reset capabilty is a
requirement. The
26 /// only exception is if you consistently use a reset control-
ler that sequences
27 /// the resets while gating both clock domains (be very care-
ful if you follow
28 /// this strategy!).
29 ///
30 /// After this disclaimer, here is how you connect the
src_rst_ni and the
31 /// dst_rst_ni of this module for power-on-reset (POR). The
src_rst_ni and
32 /// dst_rst_ni signal must be asserted SIMULTANEOUSLY (i.e.
asynchronous
33 /// assertion). Otherwise, spurious transactions could occur
in the domain
34 /// where the reset arrives later than the other. The de-as-

```

```

section of both reset
35 /// must be synchronized to their respective clock domain
(i.e. src_rst_ni must
36 /// be deasserted synchronously to the src_clk_i and
dst_rst_ni must be
37 /// deasserted synchronously to dst_clk_i.) You can use the
cc_rstgen cell in the
38 /// common_cells library to achieve this (synchronization of
only the
39 /// de-assertion). However, be careful about reset domain
crossings; If you
40 /// reset both domain asynchronously in their entirety (i.e.
POR) you are fine.
41 /// However, if you use this strategy for warm resets (some
parts of the circuit
42 /// are not reset) you might introduce metastability in this
separate
43 /// reset-domain when you assert the reset (the deassertion
synchronizer doesn't
44 /// help here).

16 /// A clock domain crossing FIFO, using gray counters.
17 ///
18 /// # Architecture
19 ///
20 /// The design is split into two parts, each one being clocked
  and reset
21 /// separately.
22 /// 1. The data to be transferred over the clock domain
  boundary is
23 /// is stored in a FIFO. The corresponding write pointer is
  managed
24 /// (incremented) in the source clock domain.
25 /// 2. The entire FIFO content is exposed over the
  `async_data` port.
26 /// The destination clock domain increments its read pointer
  er
27 /// in its destination clock domain.
28 ///
29 /// Read and write pointers are then gray coded, communicated
30 /// and synchronized using a classic multi-stage FF synchronizer
31 /// in the other clock domain. The gray coding ensures that
  only
32 /// one bit changes at each pointer increment, preventing the
33 /// synchronizer to accidentally latch an inconsistent state
34 /// on a multi-bit bus.
35 ///
36 /// The not full signal e.g. `src_ready_o` (on the sending
  side)
37 /// is generated using the local write pointer and the pessimistic
38 /// read pointer from the destination clock domain (pessimistic
39 /// because it is delayed at least two cycles because of the
  synchronizer
40 /// stages). This prevents the FIFO from overflowing.
41 ///
42 /// The not empty signal e.g. `dst_valid_o` is generated using
43 /// the pessimistic write pointer and the local read pointer
  in
44 /// the destination clock domain. This means the FIFO content
45 /// does not need to be synchronized as we are sure we are
  reading
46 /// data which has been written at least two cycles earlier.
47 /// Furthermore, the read select logic into the FIFO is completely
48 /// clocked by the destination clock domain which avoids
49 /// inefficient data synchronization.
50 ///
51 /// The FIFO size must be powers of two, which is why its
  depth is
52 /// given as 2**LogDepth. LogDepth must be at least 1.
53 ///
54 /// # Reset Behavior!!
55 ///
56 /// This module must not be used if warm reset capability is a
  requirement. The
57 /// only exception is if you consistently use a reset controller
  that sequences
58 /// the resets while gating both clock domains (be very careful
  if you follow
59 /// this strategy!). If you need warm reset/clear/flush capability,

```

```

  ility, use (AND
60 /// CAREFULLY READ THE DESCRIPTION) the
  cc_cdc_fifo_gray_clearable module.
61 ///
62 /// After this disclaimer, here is how you connect the
  src_rst_ni and the
63 /// dst_rst_ni of this module for power-on-reset (POR). The
  src_rst_ni and
64 /// dst_rst_ni signal must be asserted SIMULTANEOUSLY (i.e.
  asynchronous
65 /// assertion). Otherwise, spurious transactions could occur
  in the domain
66 /// where the reset arrives later than the other. The de-assertion
  of both reset
67 /// must be synchronized to their respective clock domain
  (i.e. src_rst_ni must
68 /// be deasserted synchronously to the src_clk_i and
  dst_rst_ni must be
69 /// deasserted synchronously to dst_clk_i.) You can use the
  cc_rstgen cell in the
70 /// common_cells library to achieve this (synchronization of
  only the
71 /// de-assertion). However be careful about reset domain
  crossings; If you
72 /// reset both domain asynchronously in their entirety (i.e.
  POR) you are fine.
73 /// However, if you use this strategy for warm resets (some
  parts of the circuit
74 /// are not reset) you might introduce metastability in this
  separate
75 /// reset-domain when you assert the reset (the deassertion
  synchronizer doesn't
76 /// help here).
77 ///
78 /// # Constraints
79 ///
80 /// We need to make sure that the propagation delay of the
81 /// data, read and write pointer is bound to the minimum of
82 /// either the sending or receiving clock period to prevent
83 /// an inconsistent state to be latched (if for example the
  one
84 /// bit of the read/write pointer have an excessive delay).
85 /// Furthermore, we should deactivate setup and hold checks on
  the asynchronous signals.
86 ///
87 /// ...
88 ///

17 /// A clock domain crossing FIFO, using gray counters.
18 ///
19 /// # Architecture
20 ///
21 /// The design is split into two parts, each one being clocked
and reset
22 /// separately.
23 /// 1. The data to be transferred over the clock domain
boundary is
24 /// is stored in a FIFO. The corresponding write pointer is
managed
25 /// (incremented) in the source clock domain.
26 /// 2. The entire FIFO content is exposed over the
`async_data` port.
27 /// The destination clock domain increments its read point-
er
28 /// in its destination clock domain.
29 ///
30 /// Read and write pointers are then gray coded, communicated
31 /// and synchronized using a classic multi-stage FF synchron-
izer
32 /// in the other clock domain. The gray coding ensures that
only
33 /// one bit changes at each pointer increment, preventing the
34 /// synchronizer to accidentally latch an inconsistent state
35 /// on a multi-bit bus.
36 ///
37 /// The not full signal e.g. `src_ready_o` (on the sending
side)
38 /// is generated using the local write pointer and the pessim-
istic
39 /// read pointer from the destination clock domain (pessimist-
ic
40 /// because it is delayed at least two cycles because of the
synchronizer
41 /// stages). This prevents the FIFO from overflowing.
42 ///
43 /// The not empty signal e.g. `dst_valid_o` is generated using
44 /// the pessimistic write pointer and the local read pointer

```

```

in
45 /// the destination clock domain. This means the FIFO content
46 /// does not need to be synchronized as we are sure we are
reading
47 /// data which has been written at least two cycles earlier.
48 /// Furthermore, the read select logic into the FIFO is com-
pletely
49 /// clocked by the destination clock domain which avoids
50 /// inefficient data synchronization.
51 ///
52 /// The FIFO size must be powers of two, which is why its
depth is
53 /// given as 2**LogDepth. LogDepth must be at least 1.
54
55 /// Reset Behavior:
56 ///
57 /// In contrast to the cc_cdc_fifo_gray version without clear
signal, this module
58 /// supports one-sided warm resets (asynchronously and syn-
chronously). The way
59 /// this is implemented is described in more detail in the
cc_cdc_reset_ctrlr
60 /// module. To summarize a synchronous clear request i.e. src/
dst_clear_i will
61 /// cause the respective other clock domain to reset as well
without introducing
62 /// any spurious transactions. This is accomplished by an in-
ternal module
63 /// (cc_cdc_reset_ctrlr) the starts a reset sequence on both
sides of the CDC in
64 /// lock-step that first isolates the CDC from the outside
world and then resets
65 /// it. The reset sequencer provides the following behavior:
66 /// 1. There are no spurious invalid or duplicated transac-
tions regardless how
67 /// the individual sides are reset (can also happen roughly
simultaneously)
68 /// 2. The FIFO becomes unready at the src side in the next
cycle after
69 /// synchronous reset request until the reset sequence is
completed. Some of
70 /// the pending transactions might still complete (if the
dst accepts at the
71 /// exact time the reset is request on the src die), some
of them will be
72 /// dropped (of course still guaranteeing FIFO order).
73 /// 3. During the reset sequence the dst might withdraw the
valid signal. This
74 /// might violate higher level protocols. If you need this
feature you would
75 /// have to patch the existing implementation to wait with
the isolate_ack
76 /// assertion until all open handshakes were acknowledged.
77 /// 4. If the parameter ClearOnAsyncReset is enabled, the same
behavior as
78 /// above is also valid for asynchronous resets on either
side. However, this
79 /// increases the minimum number of synchronization stages
(SyncStages
80 /// parameter) from 2 to 3 (read the cc_cdc_reset_ctrlr
header to figure out
81 /// why).
82 ///
83 ///
84 /// # Constraints
85 ///
86 /// We need to make sure that the propagation delay of the
data, read and write
87 /// pointer is bound to the minimum of either the sending or
receiving clock
88 /// period to prevent an inconsistent state to be latched (if
for example the
89 /// one bit of the read/write pointer have an excessive
delay). Furthermore, we
90 /// should deactivate setup and hold checks on the asynchron-
ous signals.
91 ///
92 /// async_data, async_wptr, and async_rptr are the FIFO stor-
age and pointer CDCs
93 /// for the actual data path. async_reset_src2dst_req,
94 /// async_reset_dst2src_ack, async_reset_src2dst_next_phase,
95 /// async_reset_dst2src_req, async_reset_src2dst_ack, and
96 /// async_reset_dst2src_next_phase are the CDCs for the clear-
ing state machines.
97 ///

16 // Description: CDC Clear Signaling Synchronization
17 // Coordinate clear and isolate sequencing between two CDC
clock domains so
18 // one-sided reset or clear requests do not break the protec-
ted CDC protocol.
19 //
20 // Detailed Description:
21 // This module is mainly used internally to synchronize the
clear requests
22 // between both sides of a CDC module. It aims to solve the
problem of
23 // initiating a CDC clear, reset one-sidedly without running
into
24 // reset-domain-crossing issues and breaking CDC protocol as-
sumption.
25 //
26 // Problem Formulation:
27 //

28 // CDC implementations usually face the issue that one side of
the CDC must not
29 // be cleared without clearing the other side. E.g. clearing
the write-pointer
30 // without clearing the read-pointer in a gray-counting CDC
FIFO results in an
31 // invalid fill-state an may cause spurious transactions of
invalid data to be
32 // propagated accross the CDC. A similar effect is caused in
2-phase CDC
33 // implementations.
34 //

35 // A naive mitigation technique would be to reset both domains
asynchronously
36 // with the same reset signal. This will cause intra-clock do-
main RDC issues
37 // since the asynchronous clear event (assertion of the reset
signal) might
38 // happen close to the active edge of the CDC's periphery and
thus might induce

39 // metastability. A better, but still flawed approach would be to
naively
40 // synchronize assertion AND deassertion (the usual rst sync
only synchronize
41 // deassertion) of the resets into the respective other do-
main. However, this
42 // might cause the classic issue of fast-to-slow clock domain
crossing where the
43 // clear signal is not asserted long enough to be captured by
the receiving
44 // side. The common mitigation strategy is to use a feedback
acknowledge signal
45 // to handshake the reset request into the other domain. One
even more peculiar
46 // corner case this approach might suffer is the scenario
where the synchronized

47 // clear signal arrives at the other side of the CDC within or
even worse after

48 // the same clock cylice that the other domain crossing signals
(e.g. read/write
49 // pointers) are cleared. In this scenario, multiple signals
change within the
50 // same clock cycle and due to metastability we cannot be
sure, that the other
51 // side of the CDC sees the reset assertion before the first
bits of e.g. the
52 // write/read pointer start to switch to their reset state.
Care must also be

53 // taken to handle the corner cases where both sides are reset
simultaneously or
54 // the case where one side leaves reset earlier than the oth-
er.
55 //
56 // How this Module Works
57 //
58 // This module has two interfaces, the 'a' side and the 'b'
side. Each side can
59 // be triggered using the a/b_clear_i signal or (optionally)
by the asynchronous
60 // a/b_rst_ni. Once e.g. 'a' is triggered it will initiate a
clear sequence that
61 // first asserts an 'a_isolate_o' signal, waits until the ex-
ternal circuitry
62 // acknowledges isolation using the 'a_isolate_ack_i'. Then
the module asserts
63 // the 'a_clear_o' signals before some cycles later, the isol-
ate signal is
64 // deasserted. This sequence ensures that no transactions can
arrive to the CDC

65 // while the state is cleared. Now the important part is, that
those four phases
66 // (asser isolate, assert clear, deassert clear, deassert
isolate) are mirrored
67 // on the other side ('b') in lock-step. The cc_cdc_re-

```

```

set_ctrlr module uses a
68 // dedicated 4-phase handshaking CDC to transmit the current
phase of the clear
69 // sequence to the other domain. We use a 4-phase rather than
a 2-phase CDC to
70 // avoid the issues of one-sided async reset that might trig-
ger spurious
71 // transactions. Furthermore, the 4-phase CDC within this mod-
ule is operated in
72 // a special mode: Decoupled=0 ensures that there are no in-
flight transactions.
73 // The src side only consumes the item once the destination
side acknowledged
74 // the reception. This property is required to transition
through the phases in

75 // lock-step. Furthermore, (SendResetMsg=1) will cause the src
side of the
76 // 4-phase CDC to immediately initiate the isolation phase in
the dst domain

77 // upon asynchronous reset regardless how long the async reset
stays asserted or
78 // whether the source clock is gated. Both sides of this mod-
ule independently

79 // generate the sequence signals as an initiator (triggered by
the clear_i or
80 // rst_ni signal) or receiver (triggered for the other side).
The or-ed version
81 // of initiator and receiver are used to generate the actual
a/b_isolate_o and

82 // a/b_clear_o signal. That way, it doesn't matter wheter both
sides
83 // simultanously trigger a clear sequence, proper sequencing
is still
84 // guaranteed.
85 //
86 // The time it takes to complete an entire clear sequence can
be bounded as follows:
87 //
88 //  $t_{clear} \leq 20 \cdot T + 16 \cdot SyncStages \cdot T$ , with  $T = \max(T_a, T_b)$ 
(clock periods of src and dst)
89 //
90 // How to Use the Module
91 //
92 // Instantiate the module within your CDC and connect a/
b_clk_i, the
93 // asynchronous a/b_rst_ni and the synchronous a/b_clear_i
signals. The 'a' and

94 // 'b' port are entirely symetric so it doesn't matter whether
you connect src
95 // to 'a' or 'b'. If you enable support for async reset
96 // (ClearOnAsyncReset==1), parametrize the number of synchron-
ization stages

97 // (for metastability resolution) to be strictly less than the
latency of the
98 // CDC. E.g. if your CDC uses 3 (the minimum) sync stages,
parametrize this
99 // module with SyncStages < 2! Your CDC must implement a src/
dst_clear_i port
100 // that SYNCHRONOUSLY clears all FFs on the respective side.
Connect the CDC's

101 // src/dst_clear ports to this module's a/b_clear_o port. Once
the a/b_isolate_o
102 // signal is asserted, the respective CDC side (src/dst) must
be isolated from
103 // the outside world (i.e. must no longer accept any transac-
tion on the src side
104 // and cease presenting or even withdrawing data on the dst
side). Once your CDC
105 // side is isolated (depending on protocol this might take
several cycles),
106 // assert the a/b_isolate_ack_i signal.
107 //
108 // include "common_cells/registers.svh"
109 //

217
218     /// The module is split into two parts. The initiator part
219     consists of an FSM
220     /// that is triggered by the clear_i signal and transitions
221     through reset
222     /// sequence. During those transitions, the `initiat-
223     or_isolate_out` and
224     /// `initiator_clear_out` signals are asserted appropriately.
225
226     /// The receiver part receives the state transitions from the
227     other clock
228     /// domain (initiator part of the `cc_cdc_reset_ctrlr_half`

```

```

instance in the other
226     /// clock domain) and asserts the `receiver_isolate_out` and
227     /// `receiver_clear_out` appropriately (considering the
228     `isolate_ack_i`
229     /// signal).
230     /// In both, the initiator and the receiver part, the re-
231     spective FSM
232     /// transitions through 4 phases. In the ISOLATE phase, the
233     isolate signal is
234     /// asserted and the connected CDCs are expected to block all
235     further
236     /// interactions with the outside world and acknowledge the
237     isolation with the
238     /// isolate_ack_i signal. In the CLEAR phase, the clear sig-
239     nal is asserted
240     /// which resets the internal state of the CDC while keeping
241     the isolate signal
242     /// asserted. In the POST_CLEAR phase, the clear signal is
243     deasserted. Finally,
244     /// when returning to the IDLE phase, the isolate signal is
245     deasserted to
246     /// continue normal operation. The FSM uses a dedicated 4-
247     phase handshaking CDC
248     /// to transition between the phases in lock-step and trans-
249     mits the current
250     /// state to the other domain to avoid issues if the other
251     domain is reset

1 //-----
2 // Title : Configurable Integer Clock Divider
3 //
4 // File : cc_clk_int_div.v Author : Manuel Eggimann <meggim-
mann@iis.ee.ethz.ch>
5 // Created : 17.03.2022
6 //
7 // Description :
8 //
9 // This module implements an at runtime configurable integer
10 // clock divider that
11 // always generates clean 50% duty cycle output clock. Clock
12 // divider setting
13 // changes are handshaked and during the transitioning phase
14 // between cc_clk_div
15 // value changes, the output clock is gated to prevent clock
16 // glitches and no
17 // other cc_clk_div change request is accepted. clk_o remains
18 // gated for at most
19 // 3x<new clk period> clk_i cycles. If the new div_i value
20 // equals the currently
21 // configured value, the clock is not gated and the handshake
22 // is immediately
23 // granted. It is thus safe to statically tie the valid signal to
24 // logic high if
25 // we can guarantee, that the div_i value remains stable long
26 // enough (upper
27 // limit 2 output clock cycles).
28 //
29 // The `en_i` signal can be used to enable or disable the out-
30 // put clock in a safe
31 // manner.
32 //
33 // If a div value of 0 or 1 is requested, the input clock is
34 // feed through to the
35 // output clock. However, the same gating rules apply (again
36 // to prevent
37 // glitches).
38 //
39 // If test_mode_en_i is asserted, the output clock gate is by-
40 // passed entirely and
41 // clk_o will always be directly driven by clk_i. Use this

```

```

mode for DFT of the
29 // downstream logic.
30 //
31 // Parameters:
32 //
33 // DivValueWidth: The number of bits to use for the internal
34 // counter. Defines the maximum division factor.
35 //
36 // DefaultDivValue: The default division factor to use after
37 // reset. Use this
38 // parameter and tie div_valid_i to zero if you don't need at
39 // runtime
40 // configurability. An elaboration time error will be issued
41 // if the supplied
42 // default div value is not representable with DivValueWidth
43 // bits.
44 //
45 // EnableClockInReset: If 1'b1, the clock gate will be enabled
46 // during reset
47 // which allows the cc_clk_int_div instance to bypass the
48 // clock during reset, IFF
49 // the DefaultDivValue is 1. For all other DefaultDivValues,
50 // the output
51 // clock will not be available until rst_ni is deasserted!
52 //
53 // IMPORTANT!!!
54 //
55 // All clock gating/logic within this design is performed by
56 // dedicated clock logic
57 // tech cells. By default the common_cell library uses the be-
58 // havioral models in
59 // the `tech_cells_generic` repository. However, for synthesis
60 // these cells need to be
61 // mapped to dedicated cells from your standard cell library,
62 // preferably ones
63 // that are designed for clock logic (they have balanced rise
64 // and fall time).
65 // During synthesis you furthermore have to properly set
66 // `dont_touch` or
67 // `size_only` attributes to prevent the logic synthesizer
68 // from replacing those
69 // cells with regular logic gates which could end up being
70 // glitchty!
71 //

1 //-----
2 // Title : Static Integer Clock Divider
3 //-----
4 // File : cc_clk_int_div_static.sv
5 // Author : Manuel Eggimann <meggimann@iis.ee.ethz.ch>
6 // Created : 08.05.2023
7 //-----
8 // Description :
9 //
10 // This module implements a static arbitrary integer divider.
11 // Static in this
12 // case means, the divider value is constant at elaboration
13 // time (SV parameter).
14 // It supports arbitrary integer division with a guaranteed
15 // 50% duty cycle for
16 // odd and even division.
17 //
18 // Internally, this module is wrapper around the "at-runtime"
19 // configurable

```

```

16 // `cc_clk_int_div` module. If you need to change the division
factor at-runtime you

17 // should directly use `cc_clk_int_div` instead. However if all
you need is a single
18 // division factor this module provides a convenience wrapper
for you with a
19 // simplified interface.
20 //
21 // The `en_i` signal can be used to enable or disable the out-
put clock in a safe
22 // manner (there is an internal, glitch-free clock gate).
23 //
24 // Parameters:
25 //
26 // DivValue: The integer value by which the clock shall be di-
vided. Must be
27 // non-zero integer smaller than 2^32-1.
28 //

29 // EnableClockInReset: If 1'b1, the clock gate will be enabled
during reset
30 // which allows the cc_clk_int_div instance to bypass the
clock during reset, IFF
31 // the DefaultDivValue is 1. For all other DefaultDivValues,
the output
32 // clock will not be available until rst_ni is deasserted!
33 //
34 // IMPORTANT!!!
35 //
36 // All clock gating/logic within this design is performed by
dedicated clock
37 // logic tech cells. By default the common_cell library uses
the behavioral

38 // models in the `tech_cells_generic` repository. However, for
synthesis these
39 // cells need to be mapped to dedicated cells from your stand-
ard cell library,
40 // preferably ones that are designed for clock logic (they
have balanced rise
41 // and fall time). During synthesis you furthermore have to
properly set

42 // `dont_touch` or `size_only` attributes to prevent the logic
synthesizer from
43 // replacing those cells with regular logic gates which could
end up being
44 // glitchty!
45 //

4 // File            : cc_clk_mux_glitch_free.sv
5 // Author           : Manuel Eggimann <meggimann@iis.ee.ethz.ch>
6 // Created          : 10.12.2022
7 //-----
8 // Description :
9 //
10 // This module allows glitch free clock multiplexing between N
arbitrary input
11 // clock with completely unknown phase relation ships. The
module will make
12 // sure to first synchronize the clock multiplexer signal to
the relevant clock
13 // domains and ensures glitch free switching between the
source clock and the
14 // new target clock by silencing the output at appropriate
times. The clock
15 // signals themselves only pass through: 1 clock-gate, 1 N-in-
put clock-OR Gate,
16 // 1 2-input clock mux. All these cells are referenced from
the tech_cells
17 // repository and thus no conventional logic gate is directly
in the clock path.
18
19 // The correctness of this module is based on the following
assumptions:
20 // 1. The select signal stays stable for a duration of at
least min(clks_i
21 // period)
22 // 2. Glitches on the select signal are shorter than
min(clks_i) - t_setup

23 // 3. During a transition from clock input a to clock input b,
both clocks have
24 // a stable period.
25 //
26 // A clock switching procedure from clock a to clock b has the
following timing behavior:
27 // 1. After at most NumSyncStages clock cycle of clock a, the
output clock is
28 // disabled with its next falling edge.
29 // 2. After clock cycle of clock a and another NumSyncStages
clock cycles of clock b, the output is
30 // enabled with the next rising edge of clock B.
31 //
32 // So in total, an upper bound for the worst case clock
switching delay is 2x
33 // NumSyncStages x max(clock_periods)
34 //
35 // The design has a parameter (ClockDuringReset) that allows
the clock
36 // multiplexer to propagate the selected clock even during re-
set assertion.
37 // However, during reset assertion the glitch filtering and
the synchronization
38 // registers are bypassed (since they are frozen in reset
state). Thus no glitch
39 // filtering is performed during reset. This is ok if the
async_sel_i signal
40 // stays constant during reset assertion. Once you deassert
the reset, regular
41 // glitch filtering and synchronization will kick in. However,
you must wait for
42 // at least 1x max(input clock periods) before changing the
async_sel_i after a
43 // reset to be sure the switch to regular operation has com-
pleted. During the
44 // transition from async_reset operation to regular operation
there will be a
45 // short phase where the clock is gated (similar to what hap-
pens when you switch
46 // from one clock to the other).
47 //
48 // IMPORTANT!!!
49 //
50 // All clock gating/logic within this design is performed by

```

```

dedicated clock
51 // logic tech cells. By default the common_cell library uses
the behavioral

52 // models in the `tech_cells_generic` repository. However, for
synthesis these
53 // cells need to be mapped to dedicated cells from your stand-
ard cell library,
54 // preferably ones that are designed for clock logic (they
have balanced rise
55 // and fall time). During synthesis you furthermore have to
properly set

56 // `dont_touch` or `size_only` attributes to prevent the logic
synthesizer from
57 // replacing those cells with regular logic gates which could
end up being
58 // glitchy!
59 //

95 // For each input, we generate an enable signal that enables
the clock

96 // propagation through an N-input clock OR gate. The crucial
and most critical
97 // part is to make sure that these clock enable signal
transitions are
98 // non-overlapping and have enough timing separation to pre-
vent any glitches

99 // on the clock output during the transition. We ensure this as
follows:
100 //
101 // 1. Decode the sel_i input to a onehot signal.
102 // 2. For each clock input, take the correspondi onehot sig-
nal. For each clock
103 // input we also have a correspondding output clock enable
signal that
104 // controls the corresponding clock's clk gate. We thus and-
gate the one-hot
105 // signal of the current clock with the inverse of every
other clocks enable
106 // signal. In other words, we only allow the propagation of
the onehot enable
107 // signal if the clock is currently disabled.
108 // 3. Filter any glitches on this and-gated signal by
passing it through a
109 // flip-flop clocked by the current clock and and-gating
both the output and
110 // the input. I.e. the output is only becomes active if the
signal stays
111 // stable HIGH for at least one clock period.

```

```

112 // 4. Synchronize this glitch-filtered signal into the cur-
rent clock domain
113 // with an M-stage synchronizer.
114 // 5. Use this synchronized signal as the enable signal for
a glitch-free
115 // clock gate.
116 // 7. Feed the output of the clock gate to an N-input clock-
AND gate.
117 // 8. Latch the gate enable signal with an active low latch
before using the
118 // signal as a gating signal for the other clock input's
onehot signal.

AXI4 상호연결

What this is. AXI4 crossbars, multiplexers, demultiplexers, cuts and error slaves.

Why it exists. Because AXI is the de facto SoC interconnect, and because its ordering rules — ordering guaranteed only within an ID — shape every verification component that touches it.

Undergraduate review · EECS concepts. Channel-based protocols; out-of-order completion; transaction identifiers; deadlock avoidance in interconnect.

Graduate · Practice note. A scoreboard for AXI needs **one queue per ID**. A single queue both reports false failures on legal reordering and accepts genuine intra-ID violations.

15 /// Filter atomic operations (ATOPs) in a protocol-compliant
  manner.
16 ///
17 /// This module filters atomic operations (ATOPs), i.e., write
  transactions that have a non-zero
18 /// `aw_atop` value, from its `slv` to its `mst` port. This
  module guarantees that:
19 ///
20 /// 1) `aw_atop` is always zero on the `mst` port;
21 ///
22 /// 2) write transactions with non-zero `aw_atop` on the `slv`
  port are handled in conformance with
23 /// the AXI standard by replying to such write transactions
  with the proper B and R responses.
24 /// The response code on atomic operations that reach this
  module is always SLVERR
25 /// (implementation-specific, not defined in the AXI stand-

```

```

ard).
26 ///
27 /// ## Intended usage
28 /// This module is intended to be placed between masters that
may issue ATOPs and slaves that do not
29 /// support ATOPs. That way, this module ensures that the AXI
protocol remains in a defined state on
30 /// systems with mixed ATOP capabilities.
31 ///
32 /// ## Specification reminder
33 /// The AXI standard specifies that there may be no ordering
requirements between different atomic
34 /// bursts (i.e., a burst started by an AW with ATOP other
than 0) and none between atomic bursts

35 /// and non-atomic bursts [E2.1.4]. That is, **an atomic burst
may never have the same ID as any
36 /// other write or read burst that is in-flight at the same
time**.
