5 // AES cipher core implementation
6 //
7 // This module contains the AES cipher core including, state
register, full key and decryption key
8 // registers as well as key expand module and control unit.
9 //
10 //
11 // Masking
12 // -----
13 //
14 // If the parameter "Masking" is set to one, first-order mask-
ing is applied to the entire
15 // cipher core including key expand module. For details, see
Rivain et al., "Provably secure
16 // higher-order masking of AES" available at https://
eprint.iacr.org/2010/441.pdf .
17 //
18 //
19 // Details on the data formats
20 // -----
21 //
22 // This implementation uses 4-dimensional SystemVerilog arrays to
represent the AES state:
23 //
24 //   logic [3:0][3:0][7:0] state_q [NumShares];
25 //
26 // The fourth dimension (unpacked) corresponds to the differ-
ent shares. The first element holds the
27 // (masked) data share whereas the other elements hold the
masks (masked implementation only).
28 //
29 // The three packed dimensions correspond to the 128-bit state
matrix per share. This
30 // implementation uses the same encoding as the Advanced En-
cryption Standard (AES) FIPS Publication
31 // 197 available at https://www.nist.gov/publications/ad-
vanced-encryption-standard-aes (see Section
32 // 3.4). An input sequence of 16 bytes (128-bit, left most
byte is the first one)
33 //
34 //   b0 b1 b2 b3 b4 b5 b6 b7 b8 b9 b10 b11 b12 b13 b14 b15
35 //

```

```

35 // is mapped to the state matrix as
36 //
37 // [ b0 b4 b8 b12 ]
38 // [ b1 b5 b9 b13 ]
39 // [ b2 b6 b10 b14 ]
40 // [ b3 b7 b11 b15 ] .
41 //
42 // This is mapped to three packed dimensions of SystemVerilog
array as follows:
43 // - The first dimension corresponds to the rows. Thus,
state_q[0] gives
44 // - The first row of the state matrix [ b0 b4 b8
b12 ], or
45 // - A 32-bit packed SystemVerilog array 32h'{ b12, b8, b4,
b0 }.
46 //
47 // - The second dimension corresponds to the columns. To access
complete columns, the state matrix
48 // must be transposed first. Thus state_transposed =
aes_pkg::aes_transpose(state_q) and then
49 // state_transposed[1] gives
50 // - The second column of the state matrix [ b4 b5 b6
b7 ], or
51 // - A 32-bit packed SystemVerilog array 32h'{ b7, b6, b5,
b4 }.
52 //
53 // - The third dimension corresponds to the bytes.
54 //
55 // Note that the CSRs are little-endian. The input sequence
above is provided to 32-bit DATA_IN_0 -
56 // DATA_IN_3 registers as
57 // MSB LSB
58 // - DATA_IN_0 32h'{ b3, b2, b1, b0 }
59 // - DATA_IN_1 32h'{ b7, b6, b4, b4 }
60 // - DATA_IN_2 32h'{ b11, b10, b9, b8 }
61 // - DATA_IN_3 32h'{ b15, b14, b13, b12 } .
62 //
63 // The input state can thus be obtained by transposing the
content of the DATA_IN_0 - DATA_IN_3
64 // registers.
65 //
66 // Similarly, the implementation uses a 3-dimensional array to
represent the AES keys:
67 //
68 // logic [7:0][31:0] key_full_q [NumShares]
69 //
70 // The third dimension (unpacked) corresponds to the different
shares. The first element holds the
71 // (masked) key share whereas the other elements hold the
masks (masked implementation only).
72 // The two packed dimensions correspond to the 256-bit key per
share. This implementation uses
73 // the same encoding as the Advanced Encryption Standard (AES)
FIPS Publication
74 // 197 available at https://www.nist.gov/publications/advanced-encryption-standard-aes .
75 //
76 // The first packed dimension corresponds to the 8 key words.
The second packed dimension
77 // corresponds to the 32 bits per key word. A key sequence of
32 bytes (256-bit, left most byte is
78 // the first one)
79 //
80 // b0 b1 b2 b3 b4 b5 b6 b7 b8 b9 b10 b11 b12 b13 b14
b15 ... b28 b29 b30 b31
81 //
82 // is mapped to the key words and registers (little-endian) as
83 // MSB LSB
84 // - KEY_SHARE0_0 32h'{ b3, b2, b1, b0 }
85 // - KEY_SHARE0_1 32h'{ b7, b6, b4, b4 }
86 // - KEY_SHARE0_2 32h'{ b11, b10, b9, b8 }
87 // - KEY_SHARE0_3 32h'{ b15, b14, b13, b12 }
88 // - KEY_SHARE0_4 32h'{ . . . }
89 // - KEY_SHARE0_5 32h'{ . . . }
90 // - KEY_SHARE0_6 32h'{ . . . }
91 // - KEY_SHARE0_7 32h'{ b31, b30, b29, b28 } .
92 //

349     //
350     // The masking PRNG is used for generating both the PRD for
the S-Boxes/SubBytes operation as
351     // well as for the input data masks. When using any of the
masked Canright S-Box implementations,
352     // it is important that the SubBytes input masks (generated
by the PRNG in Round X-1) and the
353     // SubBytes output masks (generated by the PRNG in Round X)
are independent. This can be achieved
354     // by using e.g. an unrolled Bivium stream cipher primitive
inside the PRNG. Since the input data
355     // masks become the SubBytes input masks in the first round,
we select the same 8 bit lanes for
356     // the input data masks which are also used to form the Sub-
Bytes output mask for the masked
357     // Canright S-Box implementations, i.e., the 8 LSBs of the
per S-Box PRD. In particular, we have:
358     //
359     // prd_masking = { prd_key_expand, ... , sb_prd[4],
sb_out_mask[4], sb_prd[0], sb_out_mask[0] }

11 // Author: Wolfgang Roenninger <wroennin@ethz.ch>
12
13 // `cc_cb_filter`: This module implements a counting bloom
filter with parameterizable hash functions.
14 //
15 // Functionality: A counting bloom filter is a data structure
to efficiently implement
16 // set lookups. It does so by hashing its data
inputs onto multiple pointers
17 // which serve as indicators for an array of
buckets. For lookups can be
18 // false positives, but no false negatives.
19 // - Seeding: The pseudo random generators need seeds at
elaboration time to generate
20 // different hashes. In principle any combina-
tion of seeds can be used.
21 // But one should look that the hash outputs
give sufficient different patterns,
22 // such that the resulting collision rate is
low. The package `cc`
23 // contains the struct for seeding the PRG's in
the hash functions.
24 // - Lookup:
25 //   - Ports: `look_data_i`, `look_valid_o`
26 //   - Description: Lookup combinational, `look_valid_o` is
high, when `look_data_i` was
27 //   previously put into the filter.
28 // - Increment:
29 //   - Ports: `incr_data_i`, `incr_valid_i`
30 //   - Description: Put data into the counting bloom filter,
when valid is high.
31 // - Decrement:
32 //   - Ports: `decr_data_i`, `decr_valid_i`
33 //   - Description: Remove data from the counting bloom fil-
ter. Only remove data that was
34 //   previously put in, otherwise will go in a
wrong state.
35 // - Status:
36 //   - `clr_i`: Clears the filter and sets all coun-
ters to 0.
37 //   - `filter_usage_o`: How many data items are currently in
the filter.
38 //   - `filter_full_o`: Filter is full, can no longer hold
more items.
39 //   - `filter_empty_o`: Filter is empty.
40 //   - `filter_error_o`: One of the internal counters or
buckets overflowed.

14 /// A two-phase clock domain crossing.
15 ///
16 /// # Reset Behavior!!
17 ///
18 /// This module must not be used if warm reset capabilty is a
requirement. The
19 /// only exception is if you consistently use a reset control-
ler that sequences
20 /// the resets while gating both clock domains (be very care-
ful if you follow
21 /// this strategy!). If you need warm reset/clear/flush capab-
ilities, use (AND
22 /// CAREFULLY READ THE DESCRIPTION) the
cc_cdc_2phase_clearable module.
23 ///
24 /// After this disclaimer, here is how you connect the
src_rst_ni and the
25 /// dst_rst_ni of this module for power-on-reset (POR). The
src_rst_ni and
26 /// dst_rst_ni signal must be asserted SIMULTANEOUSLY (i.e.
asynchronous
27 /// assertion). Otherwise, spurious transactions could occur
in the domain
28 /// where the reset arrives later than the other. The de-as-
sertion of both reset
29 /// must be synchronized to their respective clock domain
(i.e. src_rst_ni must
30 /// be deasserted synchronously to the src_clk_i and
dst_rst_ni must be
31 /// deasserted synchronously to dst_clk_i.) You can use the
cc_rstgen cell in the
32 /// common_cells library to achieve this (synchronization of
only the
33 /// de-assertion). However, be careful about reset domain
crossings; If you
34 /// reset both domain asynchronously in their entirety (i.e.
POR) you are fine.
35 /// However, if you use this strategy for warm resets (some
parts of the circuit
36 /// are not reset) you might introduce metastability in this
separate
37 /// reset-domain when you assert the reset (the deassertion
synchronizer doen't
38 /// help here).

26 ation split)
27
28 // Description: Clearable Two-Phase CDC
29 // Transfer payloads with a two-phase handshake while coordin-
30 ating synchronous
31 // and optional asynchronous one-sided clears across source
32 and destination.
33
34 // A two-phase clock domain crossing.
35
36 // CONSTRAINT: Requires max_delay of min_period(src_clk_i,
37 dst_clk_i) through
38 // all asynchronous paths between the domains. The payload
39 CDC uses
40
41 // async_payload_req, async_payload_ack, and
42 async_payload_data for the actual
43 // data handshake. The clear sequencer CDCs use
44 async_reset_src2dst_req,
45 // async_reset_dst2src_ack, async_reset_src2dst_next_phase,
46 // async_reset_dst2src_req, async_reset_src2dst_ack, and
47 // async_reset_dst2src_next_phase to handshake the clearing
48 state machines.
49
50 //
51 //
52 // Reset Behavior:
53
54 // In contrast to the cc_cdc_2phase version without clear
55 signal, this module
56 // supports one-sided warm resets (asynchronously and syn-
57 chronously). The way

```

```

36 /// this is implemented is described in more detail in the
cc_cdc_reset_ctrlr
37 /// module. To summarize a synchronous clear request i.e. src/
dst_clear_i will
38 /// cause the respective other clock domain to reset as well
without introducing
39 /// any spurious transactions. This is accomplished by an in-
ternal module
40 /// (cc_cdc_reset_ctrlr) that starts a reset sequence on both
sides of the CDC in
41 /// lock-step that first isolates the CDC from the outside
world and then resets
42 /// it. The reset sequencer provides the following behavior:
43 /// 1. There are no spurious invalid or duplicated transac-
tions regardless how

44 /// the individual sides are reset (can also happen roughly
simultaneously)
45 /// 2. The CDC becomes unready at the src side in the next
cycle after
46 /// synchronous reset request until the reset sequence is
completed. A currently
47 /// pending transactions might still complete (if the dst
accepts at the
48 /// exact time the reset is request on the src die).
49 /// 3. During the reset sequence the dst might withdraw the
valid signal. This
50 /// might violate higher level protocols. If you need this
feature you would
51 /// have to path the existing implementation to wait with
the isolate_ack
52 /// assertion until all open handshakes were acknowledged.

53 /// 4. If the parameter ClearOnAsyncReset is enabled, the same
behavior as
54 /// above is also valid for asynchronous resets on either
side. However, this
55 /// increases the minimum number of synchronization stages
(SyncStages
56 /// parameter) from 2 to 3 (read the cc_cdc_reset_ctrlr
header to figure out
57 /// why).
58 ///

14 /// A 4-phase clock domain crossing. While this is less effi-
cient than a 2-phase
15 /// CDC, it doesn't suffer from the same issues during one
sided resets since
16 /// the IDLE state doesn't alternate with every transaction.
17 ///
18 /// Parameters: data_t - The type of the data to transmit
through the CDC.
19 ///
20 /// Decoupled - If decoupled is disabled, the 4phase cdc will
not consume the
21 /// src item until the handshake with the other side is com-
pleted. This
22 /// increases the latency of the first transaction but has no
effect on
23 /// throughput. However, critical paths might be slightly
longer. Use this mode

```

```

24 /// if you want to ensure that there are no in-flight transac-
tions within the
25 /// CDC.
26 ///
27 /// SendResetMsg - If send reset msg is enabled, the 4phase
cdc starts sending
28 /// the ResetMsg within its' asynchronous reset state. This
can be usefull if
29 /// we need to transmit a message to the other side of the CDC
immediately
30 /// during an async reset even if there is no clock available.
This mode is
31 /// required for proper functionality of the cc_cdc_re-
set_ctrlr module.
32 ///
33 /// SyncStages - Number of synchronization stages for
async_req and async_ack.
34 ///
35 /// CONSTRAINT: Requires max_delay of min_period(src_clk_i,
dst_clk_i) through
36 /// the paths async_req, async_ack, async_data.

16 /// A clock domain crossing FIFO, using gray counters.
17 ///
18 /// # Architecture
19 ///
20 /// The design is split into two parts, each one being clocked
and reset
21 /// separately.
22 /// 1. The data to be transferred over the clock domain
boundary is
23 /// is stored in a FIFO. The corresponding write pointer is
managed
24 /// (incremented) in the source clock domain.
25 /// 2. The entire FIFO content is exposed over the
`async_data` port.
26 /// The destination clock domain increments its read point-
er
27 /// in its destination clock domain.
28 ///
29 /// Read and write pointers are then gray coded, communicated
30 /// and synchronized using a classic multi-stage FF synchron-
izer
31 /// in the other clock domain. The gray coding ensures that
only
32 /// one bit changes at each pointer increment, preventing the
33 /// synchronizer to accidentally latch an inconsistent state
34 /// on a multi-bit bus.
35 ///
36 /// The not full signal e.g. `src_ready_o` (on the sending
side)
37 /// is generated using the local write pointer and the pessim-
istic
38 /// read pointer from the destination clock domain (pessimist-
ic
39 /// because it is delayed at least two cycles because of the
synchronizer
40 /// stages). This prevents the FIFO from overflowing.
41 ///
42 /// The not empty signal e.g. `dst_valid_o` is generated using
43 /// the pessimistic write pointer and the local read pointer
in
44 /// the destination clock domain. This means the FIFO content
45 /// does not need to be synchronized as we are sure we are
reading
46 /// data which has been written at least two cycles earlier.
47 /// Furthermore, the read select logic into the FIFO is com-
pletely
48 /// clocked by the destination clock domain which avoids
49 /// inefficient data synchronization.
50 ///
51 /// The FIFO size must be powers of two, which is why its
depth is
52 /// given as 2**LogDepth. LogDepth must be at least 1.
53 ///
54 /// # Reset Behavior!!
55 ///
56 /// This module must not be used if warm reset capabilty is a
requirement. The
57 /// only exception is if you consistently use a reset control-

17 /// A clock domain crossing FIFO, using gray counters.
18 ///
19 /// # Architecture
20 ///
21 /// The design is split into two parts, each one being clocked
  and reset
22 /// separately.
23 /// 1. The data to be transferred over the clock domain
  boundary is
24 /// is stored in a FIFO. The corresponding write pointer is
  managed
25 /// (incremented) in the source clock domain.
26 /// 2. The entire FIFO content is exposed over the
  `async_data` port.
27 /// The destination clock domain increments its read point-
  er
28 /// in its destination clock domain.
29 ///
30 /// Read and write pointers are then gray coded, communicated
31 /// and synchronized using a classic multi-stage FF synchron-
  izer
32 /// in the other clock domain. The gray coding ensures that
  only
33 /// one bit changes at each pointer increment, preventing the
34 /// synchronizer to accidentally latch an inconsistent state
35 /// on a multi-bit bus.
36 ///
37 /// The not full signal e.g. `src_ready_o` (on the sending
  side)
38 /// is generated using the local write pointer and the pessim-
  istic
39 /// read pointer from the destination clock domain (pessimist-
  ic
40 /// because it is delayed at least two cycles because of the
  synchronizer
41 /// stages). This prevents the FIFO from overflowing.

```

```

42 ///
43 /// The not empty signal e.g. `dst_valid_o` is generated using
44 /// the pessimistic write pointer and the local read pointer
  in
45 /// the destination clock domain. This means the FIFO content
46 /// does not need to be synchronized as we are sure we are
  reading
47 /// data which has been written at least two cycles earlier.
48 /// Furthermore, the read select logic into the FIFO is com-
  pletely
49 /// clocked by the destination clock domain which avoids
50 /// inefficient data synchronization.
51 ///
52 /// The FIFO size must be powers of two, which is why its
  depth is
53 /// given as 2**LogDepth. LogDepth must be at least 1.
54
55 /// Reset Behavior:
56 ///
57 /// In contrast to the cc_cdc_fifo_gray version without clear
  signal, this module
58 /// supports one-sided warm resets (asynchronously and syn-
  chronously). The way
59 /// this is implemented is described in more detail in the
  cc_cdc_reset_ctrlr
60 /// module. To summarize a synchronous clear request i.e. src/
  dst_clear_i will
61 /// cause the respective other clock domain to reset as well
  without introducing
62 /// any spurious transactions. This is accomplished by an in-
  ternal module
63 /// (cc_cdc_reset_ctrlr) the starts a reset sequence on both
  sides of the CDC in
64 /// lock-step that first isolates the CDC from the outside
  world and then resets
65 /// it. The reset sequencer provides the following behavior:
66 /// 1. There are no spurious invalid or duplicated transac-
  tions regardless how
67 /// the individual sides are reset (can also happen roughly
  simultaneously)
68 /// 2. The FIFO becomes unready at the src side in the next
  cycle after
69 /// synchronous reset request until the reset sequence is
  completed. Some of
70 /// the pending transactions might still complete (if the
  dst accepts at the
71 /// exact time the reset is request on the src die), some
  of them will be
72 /// dropped (of course still guaranteeing FIFO order).
73 /// 3. During the reset sequence the dst might withdraw the
  valid signal. This
74 /// might violate higher level protocols. If you need this
  feature you would
75 /// have to path the existing implementation to wait with
  the isolate_ack
76 /// assertion until all open handshakes were acknowledged.
77 /// 4. If the parameter ClearOnAsyncReset is enabled, the same
  behavior as
78 /// above is also valid for asynchronous resets on either
  side. However, this
79 /// increases the minimum number of synchronization stages
  (SyncStages
80 /// parameter) from 2 to 3 (read the cc_cdc_reset_ctrlr
  header to figure out
81 /// why).
82 ///
83 ///
84 /// # Constraints
85 ///
86 /// We need to make sure that the propagation delay of the
  data, read and write
87 /// pointer is bound to the minimum of either the sending or
  receiving clock
88 /// period to prevent an inconsistent state to be latched (if
  for example the
89 /// one bit of the read/write pointer have an excessive
  delay). Furthermore, we
90 /// should deactivate setup and hold checks on the asynchron-
  ous signals.
91 ///
92 /// async_data, async_wptr, and async_rptr are the FIFO stor-
  age and pointer CDCs
93 /// for the actual data path. async_reset_src2dst_req,
94 /// async_reset_dst2src_ack, async_reset_src2dst_next_phase,
95 /// async_reset_dst2src_req, async_reset_src2dst_ack, and
96 /// async_reset_dst2src_next_phase are the CDCs for the clear-
  ing state machines.
97 ///

16 // Description: CDC Clear Signaling Synchronization
17 // Coordinate clear and isolate sequencing between two CDC
clock domains so
18 // one-sided reset or clear requests do not break the protec-
ted CDC protocol.
19 //
20 // Detailed Description:
21 // This module is mainly used internally to synchronize the
clear requests
22 // between both sides of a CDC module. It aims to solve the
problem of
23 // initiating a CDC clear, reset one-sidedly without running
into
24 // reset-domain-crossing issues and breaking CDC protocol as-
sumption.
25 //
26 // Problem Formulation:
27 //
28 // CDC implementations usually face the issue that one side of
the CDC must not
29 // be cleared without clearing the other side. E.g. clearing
the write-pointer
30 // without clearing the read-pointer in a gray-counting CDC
FIFO results in an
31 // invalid fill-state and may cause spurious transactions of
invalid data to be
32 // propagated across the CDC. A similar effect is caused in
2-phase CDC
33 // implementations.
34 //
35 // A naive mitigation technique would be to reset both domains
asynchronously
36 // with the same reset signal. This will cause intra-clock do-
main RDC issues
37 // since the asynchronous clear event (assertion of the reset
signal) might
38 // happen close to the active edge of the CDC's periphery and
thus might induce
39 // metastability. A better, but still flawed approach would be to
naively
40 // synchronize assertion AND deassertion (the usual rst sync
only synchronize
41 // deassertion) of the resets into the respective other do-
main. However, this
42 // might cause the classic issue of fast-to-slow clock domain
crossing where the
43 // clear signal is not asserted long enough to be captured by
the receiving
44 // side. The common mitigation strategy is to use a feedback
acknowledge signal
45 // to handshake the reset request into the other domain. One
even more peculiar
46 // corner case this approach might suffer is the scenario
where the synchronized
47 // clear signal arrives at the other side of the CDC within or
even worse after
48 // the same clock cycle that the other domain crossing signals
(e.g. read/write
49 // pointers) are cleared. In this scenario, multiple signals
change within the
50 // same clock cycle and due to metastability we cannot be
sure, that the other
51 // side of the CDC sees the reset assertion before the first
bits of e.g. the
52 // write/read pointer start to switch to their reset state.
Care must also be

```

```

53 // taken to handle the corner cases where both sides are reset
simultaneously or
54 // the case where one side leaves reset earlier than the oth-
er.
55 //
56 // How this Module Works
57 //
58 // This module has two interfaces, the 'a' side and the 'b'
side. Each side can
59 // be triggered using the a/b_clear_i signal or (optionally)
by the asynchronous
60 // a/b_rst_ni. Once e.g. 'a' is triggered it will initiate a
clear sequence that
61 // first asserts an 'a_isolate_o' signal, waits until the ex-
ternal circuitry
62 // acknowledges isolation using the 'a_isolate_ack_i'. Then
the module asserts
63 // the 'a_clear_o' signals before some cycles later, the isol-
ate signal is
64 // deasserted. This sequence ensures that no transactions can
arrive to the CDC
65 // while the state is cleared. Now the important part is, that
those four phases

```

```

66 // (asser isolate, assert clear, deassert clear, deassert
isolate) are mirrored
67 // on the other side ('b') in lock-step. The cc_cdc_re-
set_ctrlr module uses a
68 // dedicated 4-phase handshaking CDC to transmit the current
phase of the clear
69 // sequence to the other domain. We use a 4-phase rather than
a 2-phase CDC to
70 // avoid the issues of one-sided async reset that might trig-
ger spurious
71 // transactions. Furthermore, the 4-phase CDC within this mod-
ule is operated in
72 // a special mode: Decoupled=0 ensures that there are no in-
flight transactions.
73 // The src side only consumes the item once the destination
side acknowledged
74 // the reception. This property is required to transition
through the phases in

75 // lock-step. Furthermore, (SendResetMsg=1) will cause the src
side of the
76 // 4-phase CDC to immediately initiate the isolation phase in
the dst domain

77 // upon asynchronous reset regardless how long the async reset
stays asserted or
78 // whether the source clock is gated. Both sides of this mod-
ule independently

79 // generate the sequence signals as an initiator (triggered by
the clear_i or
80 // rst_ni signal) or receiver (triggered for the other side).
The or-ed version
81 // of initiator and receiver are used to generate the actual
a/b_isolate_o and

82 // a/b_clear_o signal. That way, it doesn't matter wheter both
sides
83 // simulatenously trigger a clear sequence, proper sequencing
is still
84 // guaranteed.
85 //
86 // The time it takes to complete an entire clear sequence can
be bounded as follows:
87 //
88 //  $t_{clear} \leq 20 \cdot T + 16 \cdot SyncStages \cdot T$ , with  $T = \max(T_a, T_b)$ 
(clock periods of src and dst)
89 //
90 // How to Use the Module
91 //
92 // Instantiate the module within your CDC and connect a/
b_clk_i, the
93 // asynchronous a/b_rst_ni and the synchronous a/b_clear_i
signals. The 'a' and

94 // 'b' port are entirely symetric so it doesn't matter whether
you connect src
95 // to 'a' or 'b'. If you enable support for async reset
96 // (ClearOnAsyncReset==1), parametrize the number of synchron-
ization stages

97 // (for metastability resolution) to be strictly less than the
latency of the
98 // CDC. E.g. if your CDC uses 3 (the minimum) sync stages,
parametrize this
99 // module with SyncStages < 2! Your CDC must implement a src/
dst_clear_i port
100 // that SYNCHRONOUSLY clears all FFs on the respective side.
Connect the CDC's

101 // src/dst_clear ports to this module's a/b_clear_o port. Once
the a/b_isolate_o
102 // signal is asserted, the respective CDC side (src/dst) must
be isolated from
103 // the outside world (i.e. must no longer accept any transac-
tion on the src side
104 // and cease presenting or even withdrawing data on the dst
side). Once your CDC
105 // side is isolated (depending on protocol this might take
several cycles),
106 // assert the a/b_isolate_ack_i signal.
107 //
108 // include "common_cells/registers.svh"
109

214     );
215
216
217     // How this module works:
218
219     // The module is split into two parts. The initiator part
220     // consists of an FSM
221     // that is triggered by the clear_i signal and transitions
222     // through reset
223     // sequence. During those transitions, the `initiat-
224     // or_isolate_out` and
225     // `initiator_clear_out` signals are asserted appropriately.

```

```

224 // The receiver part receives the state transitions from the
other clock
225 // domain (initiator part of the `cc_cdc_reset_ctrlr_half`
instance in the other
226 // clock domain) and asserts the `receiver_isolate_out` and
227 // `receiver_clear_out` appropriately (considering the
`isolate_ack_i`
228 // signal).
229
230 // In both, the initiator and the receiver part, the re-
spective FSM
231 // transitions through 4 phases. In the ISOLATE phase, the
isolate signal is
232 // asserted and the connected CDCs are expected to block all
further
233 // interactions with the outside world and acknowledge the
isolation with the
234 // isolate_ack_i signal. In the CLEAR phase, the clear sig-
nal is asserted
235 // which resets the internal state of the CDC while keeping
the isolate signal
236 // asserted. In the POST_CLEAR phase, the clear signal is
deasserted. Finally,
237 // when returning to the IDLE phase, the isolate signal is
deasserted to
238 // continue normal operation. The FSM uses a dedicated 4-
phase handshaking CDC
239 // to transition between the phases in lock-step and trans-
mits the current
240 // state to the other domain to avoid issues if the other
domain is reset
241 // asynchronously while a clear procedure is pending.

1 //-----
2 // Title : Configurable Integer Clock Divider
3 //-----
4 // File : cc_clk_int_div.sv Author : Manuel Eggimann <meggim-
mann@iis.ee.ethz.ch>
5 // Created : 17.03.2022
6 //-----
7 // Description :
8 //
9 // This module implements an at runtime configurable integer
clock divider that
10 // always generates clean 50% duty cycle output clock. Clock
divider setting
11 // changes are handshaked and during the transitioning phase
between cc_clk_div
12 // value changes, the output clock is gated to prevent clock
glitches and no
13 // other cc_clk_div change request is accepted. clk_o remains
gated for at most
14 // 3x<new clk period> clk_i cycles. If the new div_i value
equals the currently
15 // configured value, the clock is not gated and the handshake
is immediately
16 // granted. It is thus safe to statically tie the valid signal to
logic high if
17 // we can guarantee, that the div_i value remains stable long
enough (upper
18 // limit 2 output clock cycles).
19 //
20 // The `en_i` signal can be used to enable or disable the out-
put clock in a safe
21 // manner.
22 //
23 // If a div value of 0 or 1 is requested, the input clock is
fed through to the
24 // output clock. However, the same gating rules apply (again
to prevent
25 // glitches).
26 //

```

```

27 // If test_mode_en_i is asserted, the output clock gate is by-
passed entirely and
28 // clk_o will always be directly driven by clk_i. Use this
mode for DFT of the
29 // downstream logic.
30 //
31 // Parameters:
32 //
33 // DivValueWidth: The number of bits to use for the internal
34 // counter. Defines the maximum division factor.
35 //
36 // DefaultDivValue: The default division factor to use after
reset. Use this
37 // parameter and tie div_valid_i to zero if you don't need at
runtime
38 // configurability. An elaboration time error will be issued
if the supplied
39 // default div value is not representable with DivValueWidth
bits.
40 //

41 // EnableClockInReset: If 1'b1, the clock gate will be enabled
during reset
42 // which allows the cc_clk_int_div instance to bypass the
clock during reset, IFF
43 // the DefaultDivValue is 1. For all other DefaultDivValues,
the output
44 // clock will not be available until rst_ni is deasserted!
45 //
46 // IMPORTANT!!!
47 //
48 // All clock gating/logic within this design is performed by
dedicated clock logic
49 // tech cells. By default the common_cell library uses the be-
havioral models in

50 // the `tech_cells_generic` repository. However, for synthesis
these cells need to be
51 // mapped to dedicated cells from your standard cell library,
preferably ones
52 // that are designed for clock logic (they have balanced rise
and fall time).
53 // During synthesis you furthermore have to properly set
`dont_touch` or
54 // `size_only` attributes to prevent the logic synthesizer
from replacing those
55 // cells with regular logic gates which could end up being
glitchy!
56 //

1 //-----
2 // Title : Static Integer Clock Divider
3 //-----
4 // File : cc_clk_int_div_static.sv
5 // Author : Manuel Eggmann <meggmann@iis.ee.ethz.ch>
6 // Created : 08.05.2023
7 //-----
8 // Description :
9 //
10 // This module implements a static arbitrary integer divider.
Static in this
11 // case means, the divider value is constant at elaboration
time (SV parameter).
12 // It supports arbitrary integer division with a guaranteed
50% duty cycle for
13 // odd and even division.

```

```

14
15 // Internally, this module is wrapper around the "at-runtime"
configurable
16 // `cc_clk_int_div` module. If you need to change the division
factor at-runtime you
17 // should directly use `cc_clk_int_div` instead. However if all
you need is a single
18 // division factor this module provides a convenience wrapper
for you with a
19 // simplified interface.
20 //
21 // The `en_i` signal can be used to enable or disable the out-
put clock in a safe
22 // manner (there is an internal, glitch-free clock gate).
23 //
24 // Parameters:
25 //
26 // DivValue: The integer value by which the clock shall be di-
vided. Must be
27 // non-zero integer smaller than 2^32-1.
28 //
29 // EnableClockInReset: If 1'b1, the clock gate will be enabled
during reset
30 // which allows the cc_clk_int_div instance to bypass the
clock during reset, IFF
31 // the DefaultDivValue is 1. For all other DefaultDivValues,
the output
32 // clock will not be available until rst_ni is deasserted!
33 //
34 // IMPORTANT!!!
35 //
36 // All clock gating/logic within this design is performed by
dedicated clock
37 // logic tech cells. By default the common_cell library uses
the behavioral
38 // models in the `tech_cells_generic` repository. However, for
synthesis these
39 // cells need to be mapped to dedicated cells from your stand-
ard cell library,
40 // preferably ones that are designed for clock logic (they
have balanced rise
41 // and fall time). During synthesis you furthermore have to
properly set
42 // `dont_touch` or `size_only` attributes to prevent the logic
synthesizer from
43 // replacing those cells with regular logic gates which could
end up being
44 // glitchy!
45 //

1 //-----
2 // Title      : Glitch-free Clock Multiplexer
3 //-----
4 // File       : cc_clk_mux_glitch_free.sv
5 // Author     : Manuel Eggimann <meggimann@iis.ee.ethz.ch>
6 // Created    : 10.12.2022
7 //-----
8 // Description :
9 //
10 // This module allows glitch free clock multiplexing between N
11 // arbitrary input
12 // clock with completely unknown phase relations. The
13 // module will make
14 // sure to first synchronize the clock multiplexer signal to
15 // the relevant clock
16 // domains and ensures glitch free switching between the
17 // source clock and the
18 // new target clock by silencing the output at appropriate
19 // times. The clock
20 // signals themselves only pass through: 1 clock-gate, 1 N-in-
21 // put clock-OR Gate,
22 // 1 2-input clock mux. All these cells are referenced from
23 // the tech_cells
24 // repository and thus no conventional logic gate is directly
25 // in the clock path.
26 //
27 // The correctness of this module is based on the following
28 // assumptions:
29 // 1. The select signal stays stable for a duration of at
30 // least min(clks_i
31 // period)
32 // 2. Glitches on the select signal are shorter than
33 // min(clks_i) - t_setup
34 //
35 // 3. During a transition from clock input a to clock input b,
36 // both clocks have
37 // a stable period.
38 //
39 // A clock switching procedure from clock a to clock b has the
40 // following timing behavior:
41 // 1. After at most NumSyncStages clock cycle of clock a, the
42 // output clock is
43 // disabled with its next falling edge.
44 // 2. After clock cycle of clock a and another NumSyncStages
45 // clock cycles of clock b, the output is
46 // enabled with the next rising edge of clock B.
47 //
48 // So in total, an upper bound for the worst case clock
49 // switching delay is 2x
50 // NumSyncStages x max(clock_periods)
51 //
52 // The design has a parameter (ClockDuringReset) that allows
53 // the clock
54 // multiplexer to propagate the selected clock even during re-
55 // set assertion.
56 // However, during reset assertion the glitch filtering and
57 // the synchronization
58 // registers are bypassed (since they are frozen in reset
59 // state). Thus no glitch
60 // filtering is performed during reset. This is ok if the
61 // async_sel_i signal
62 // stays constant during reset assertion. Once you deassert
63 // the reset, regular
64 // glitch filtering and synchronization will kick in. However,
65 // you must wait for
66 // at least 1x max(input clock periods) before changing the
67 // async_sel_i after a
68 // reset to be sure the switch to regular operation has com-
69 // pleted. During the
70 // transition from async_reset operation to regular operation
71 // there will be a
72 // short phase where the clock is gated (similar to what hap-
73 // pens when you switch
74 // from one clock to the other).
75 //
76 //

```

```

48 // IMPORTANT!!!

116 //
117 // propagation through an N-input clock OR gate. The crucial
118 // and most critical
119 // part is to make sure that these clock enable signal
120 // transitions are
121 // non-overlapping and have enough timing separation to pre-
122 // vent any glitches
123 //
124 // on the clock output during the transition. We ensure this as
125 // follows:
126 //
127 // 1. Decode the sel_i input to a onehot signal.
128 // 2. For each clock input, take the correspondi onehot sig-
129 // nal. For each clock
130 // input we also have a corresponding output clock enable
131 // signal that
132 // controls the corresponding clock's clk gate. We thus and-
133 // gate the one-hot
134 // signal of the current clock with the inverse of every
135 // other clocks enable
136 // signal. In other words, we only allow the propagation of
137 // the onehot enable
138 // signal if the clock is currently disabled.
139 // 3. Filter any glitches on this and-gated signal by
140 // passing it through a
141 // flip-flop clocked by the current clock and and-gating
142 // both the output and

```

```

110 // the input. I.e. the output is only becomes active if the
signal stays
111 // stable HIGH for at least one clock period.
112 // 4. Synchronize this glitch-filtered signal into the cur-
rent clock domain
113 // with an M-stage synchronizer.
114 // 5. Use this synchronized signal as the enable signal for
a glitch-free
115 // clock gate.
116 // 7. Feed the output of the clock gate to an N-input clock-
AND gate.

15 /// Filter atomic operations (ATOPs) in a protocol-compliant
  manner.
16 ///
17 /// This module filters atomic operations (ATOPs), i.e., write
  transactions that have a non-zero
18 /// `aw_atop` value, from its `slv` to its `mst` port. This
  module guarantees that:
19 ///
20 /// 1) `aw_atop` is always zero on the `mst` port;
21 ///
22 /// 2) write transactions with non-zero `aw_atop` on the `slv`
  port are handled in conformance with
23 /// the AXI standard by replying to such write transactions
  with the proper B and R responses.
24 /// The response code on atomic operations that reach this
  module is always SLVERR
25 /// (implementation-specific, not defined in the AXI stand-
  ard).
26 ///
27 /// ## Intended usage
28 /// This module is intended to be placed between masters that
  may issue ATOPs and slaves that do not
29 /// support ATOPs. That way, this module ensures that the AXI
  protocol remains in a defined state on

```

```

30 /// systems with mixed ATOP capabilities.
31 ///
32 /// ## Specification reminder
33 /// The AXI standard specifies that there may be no ordering
  requirements between different atomic
34 /// bursts (i.e., a burst started by an AW with ATOP other
  than 0) and none between atomic bursts
35 /// and non-atomic bursts [E2.1.4]. That is, **an atomic burst
  may never have the same ID as any
36 /// other write or read burst that is in-flight at the same
  time**.

26 /// Demultiplex one AXI4+ATOP slave port to multiple AXI4+ATOP
master ports.
27 ///
28 /// The AW and AR slave channels each have a `select` input to
determine to which master port the
29 /// current request is sent. The `select` can, for example,
be driven by an address decoding module
30 /// to map address ranges to different AXI slaves.
31 ///
32 /// ## Design overview
33 ///
34 /// ![Block diagram](module.axi_demux.png "Block diagram")
35 ///
36 /// Beats on the W channel are routed by demultiplexer accord-
ing to the selection for the
37 /// corresponding AW beat. This relies on the AXI property
that W bursts must be sent in the same
38 /// order as AW beats and beats from different W bursts may
not be interleaved.
39 ///
40 /// Beats on the B and R channel are multiplexed from the mas-
ter ports to the slave port with
41 /// a round-robin arbitration tree.

11 // APB Clock Domain Crossing
12 // Author: Manuel Eggimann <eggimann@iis.ee.ethz.ch>
13 // Description: A clock domain crossing module on an APB in-
  terface. The module uses gray-counting
14 // CDC FIFOs in both directions to synchronize source side
  with destination side.
15 // Parameters:
16 // - `LogDepth`: The FIFO crossing the clock domain has
  `2^LogDepth` entries

17 // - `req_t`: APB4 request struct. See macro definition in
  `include/typedef.svh`
18 // - `resp_t`: APB4 response struct. See macro defini-
  tion in `include/typedef.svh`
19 //
20 // Ports:
21 //
22 // - `src_pclk_i`: Source side clock input signal (1-bit).

23 // - `src_preset_ni`: Source side asynchronous active low reset
  signal (1-bit).
24 // - `src_req_i`: Source side APB4 request struct, bundles
  all APB4 signals from the master (req_t).

25 // - `src_resp_o`: Source side APB4 response struct, bundles
  all APB4 signals to the master (resp_t).
26 // - `dst_pclk_i`: Destination side clock input signal (1-
  bit).
27 // - `dst_preset_ni`: Destination side asynchronous active low
  reset signal (1-bit).
28 // - `dst_req_o`: Destination side APB4 request struct,
  bundles all APB4 signals to the slave (req_t).
29 // - `dst_resp_i`: Destination side APB4 response struct,
  bundles all APB4 signals from the slave (resp_t).
30 //
31 // This file also features the module `apb_cdc_intf`. The dif-
  ference is that instead of the
32 // request and response structs it uses a `APB` interfaces.
  The parameters have the same
33 // function, however are defined in `ALL_CAPS`.

11 // APB Read-Write Registers
12 // Description: This module exposes a number of registers on
an APB interface.
13 // It responds to not mapped accesses with a
slave error.
14 // Some of the registers can be configured to be
read only.
15 // Parameters:
16 // - `NoApbRegs`: Number of registers.
17 // - `ApbAddrWidth`: Address width of `req_i.paddr`, is used
to generate internal address map.
18 // - `AddrOffset`: The address offset in bytes between the

```

```

registers. Is asserted to be a least
19 //      '32'd4', the reason is to prevent overlap in
the address map.
20 //      Each register is mapped to a 4 byte wide
address range. When this parameter
21 //      is bigger than '32'd4' there will be
holes in the address map and the module
22 //      answers with `apb_pkg::RESP_SLVERR`. It
is recommended that this value is a
23 //      power of 2, to prevent data alignment is-
sues on upstream buses.
24 // - `ApbDataWidth`: The data width of the APB4 bus, this
value can be up to '32'd32' (bit).
25 // - `RegDataWidth`: The data width of the registers, this
value has to be less or equal to
26 //      `ApbDataWidth`. If it is less the re-
gister gets zero extended for reads and
27 //      higher bits on writes get ignored.
28 // - `ReadOnly`: This flag can specify a read only re-
gister at the given register index of the
29 //      array. When in the array the correspond-
ing bit is set, the `reg_init_i` signal
30 //      at given index can be read out. Writes
are ignored if the flag is set.

31 // - `req_t`: APB4 request struct. See macro definition in
`include/typedef.svh`
32 // - `resp_t`: APB4 response struct. See macro defini-
tion in `include/typedef.svh`
33 //
34 // Ports:
35 //
36 // - `pclk_i`: Clock input signal (1-bit).
37 // - `preset_ni`: Asynchronous active low reset signal (1-
bit).
38 // - `req_i`: APB4 request struct, bundles all APB4
signals from the master (req_t).
39 // - `resp_o`: APB4 response struct, bundles all APB4
signals to the master (resp_t).
40 // - `base_addr_i`: Base address of this module, from here
the registers '0' are mapped, starting
41 //      with index '0'. All subsequent register
with higher indices have their bases
42 //      mapped with reg_index * `AddrOffset` from
this value (ApbAddrWidth-bit).
43 // - `reg_init_i`: Initialization value for each register,
when the register index is configured
44 //      as `ReadOnly[reg_index] == 1'b1` this
value is passed through directly to
45 //      the APB4 bus (Array size `NoApbRegs` *
RegDataWidth-bit).

46 // - `reg_q_o`: The current value of the register. If the
register at the array index is
47 //      read only, the `reg_init_i` value is
passed through to the respective index
48 //      (Array size `NoApbRegs` * RegDataWidth-
bit).
49 //
50 // This file also features the module `apb_regs_intf`. The
difference is that instead of the
51 // request and response structs it uses an `APB.Slave` inter-
face. The parameters have the same
52 // Function, however are defined in `ALL_CAPS`.

25 // Design Name:   OBI Wrapper for Debug Module
26 // (dm_top)
27 // Project Name:  CV32E40P
28 // Language:      SystemVeri-
29 // log
30 //
31 // Description:   Wrapper for the Debug Module (dm_top) which
32 // gives it an //
33 // OBI (Open Bus Interface) compatible inter-
34 // faces so that it //
35 // can be integrated without further glue lo-
36 // gic (other than //
37 // tie offs in an OBI compliant sys-
38 // tem.
39 //
40 // This wrapper is only intended for OBI com-
41 // pliant systems; //
42 // in other systems the existing dm_top can be
43 // used as before //
44 // and this wrapper can be ig-
45 // nored.
46 //
47 // The OBI spec is available
48 // at:
49 //
50 // - https://github.com/openhwgroup/core-v-
51 // docs/blob/master/ //
52 // cores/
53 // cv32e40p/
54 //
55 // Compared to 'logint' interfaces of dm_top
56 // the following //
57 // signals are ad-
58 // ded:
59 //
60 // - slave_* OBI inter-
61 // face:
62 //
63 // -
64 // slave_gnt_o
65 // slave_rvalid_o
66 // slave_aid_i
67 // slave_rid_o
68 //
69 // Compared to 'logint' interfaces of dm_top
70 // the following //
71 // signals have been re-
72 // named:
73 //
74 // - master_* OBI inter-
75 // face:
76 //

61   store, load and shift operations.
62   store : Data to be written is shifted to the correct posi-
63   tion in dat during init by shift_en and is presented on the data bus
64   as o_wb_dat
65   load : Data from the bus gets latched into dat during
66   i_wb_ack and is then shifted out at the appropriate time to end up in
67   the correct position in rd
68   shift : Data is shifted in during init. After that, the
69   six LSB are used as a downcounter (with bit 5 initially set to 0) that
70   trigger
71   o_sh_done when they wrap around to indicate that
72   the requested number of shifts have been performed

172
173 generate
174 /*
175     Because SERV is 32-bit bit-serial we need a counter
than can count 0-31
176
177 to keep track of which bit we are currently processing.
o_cnt and cnt_r
178 are used together to create such a counter.
179 The top three bits (o_cnt) are implemented as a normal
counter, but
180
181 instead of the two LSB, cnt_r is a 4-bit shift register
which loops 0-3
182 When cnt_r[3] is 1, o_cnt will be increased.
183
184 The counting starts when the core is idle and the
i_rf_ready signal
185 comes in from the RF module by shifting in the
i_rf_ready bit as LSB of
186 the shift register. Counting is stopped by using
o_cnt_done to block the
187 bit that was supposed to be shifted into bit 0 of
cnt_r.
188
189 There are two benefit of doing the counter this way
190
191 1. We only need to check four bits instead of five when
we want to check
192 if the counter is at a certain value. For 4-LUT archi-
tectures this means
193 we only need one LUT instead of two for each comparis-
on.
194 2. We don't need a separate enable signal to turn on
and off the counter
195 between stages, which saves an extra FF and a unique
control signal. We
196 just need to check if cnt_r is not zero to see if the
counter is
197 currently running

1. ZipCPU_wb2axip/rtl/addrdecode.v (467 lines)

```

1 ///////////////////////////////////////////////////////////////////
2 //
3 // Filename:   rtl/addrdecode.v
4 // {{{
5 // Project:    WB2AXISP: bus bridges and other odds and ends
6 //
7 // Purpose:    Supports bus crossbars by answering the ques-
8 //             tion, which slave
9 //             does the current address need to be routed to? Re-
10 //             quests are
11 //             pipelined using valid!/stall handshaking. For those
12 //             familiar with
13 //             AXI, READY!=STALL. The outgoing stream is identical to
14 //             the incoming
15 //             one, save for the (new) o_decode field. This is a bit-
16 //             mask containing
17 //             one bit for each slave that the request might be routed
18 //             to, and one
19 //             extra bit to indicate no slaves matched.
20 //             The keys to the operation of this module are found in
21 //             the two
22 //             parameters, SLAVE_ADDR and SLAVE_MASK.
23 //             SLAVE_ADDR specifies the address of the slave in ques-
24 //             tion. It's a large
25 //             array, with one address (i.e. one set of AW
26 //             bits) for each
27 //             potential slave address region.
28 //             SLAVE_MASK specifies which of the bits in SLAVE_ADDR
29 //             need to match in
30 //             order to route a request to a that slave.
31 //             It's important to guarantee that no two slaves will
32 //             ever map to the
33 //             same address, and likewise any given slave may only map to
34 //             a single
35 //             address region.
36 //             Incidentally, the algorithm forces all slaves to have
37 //             an address
38 //             aligned with their memory size. Hence a 2GB memory
39 //             must have an
40 //             address (range) of either 0-2GB, 2GB-4GB, 4GB-6GB,
41 //             etc. However, a
42 //             second slave having only 8kB of memory may be placed at
43 //             0-8kB,
44 //             8-16kB, 16-24kB, etc. For logic minimization purposes, it
45 //             is often to
46 //             the advantage of the bus compositor to minimize the
47 //             number of mask
48 //             bits, and hence 8kB slaves may be aliased to many
49 //             places in memory.
50 //             Bus composition and address assignment, however, are
51 //             both outside of
52 //             the scope of the operation of this module.

45     // LGFIFO is the log based-two of the number of
46     // entries
47     // in the FIFO, log_2(fifo size)
48     // parameter LGFIFO = 3,
49     //
50     // WIDTH is the number of data bits in each
51     // entry
52     // parameter WIDTH = 16,
53     //
54     // NFF is the number of flip flops used to
55     // cross clock domains.
56     // 2 is a minimum. Some applications appreci-
57     // ate the better
58     // parameter NFF = 2,
59     //
60     // This core can either write on the positive
61     // edge of the clock
62     // or the negative edge. Set WRITE_ON_POSEDGE
63     // (the default)
64     // to write on the positive edge of the clock.
65     // parameter [0:0] WRITE_ON_POSEDGE = 1'b1,
66     //
67     // Many logic elements can read from memory
68     // asynchronously.
69     // This capability is sometimes known as "Dis-
70     // tributed RAM" or
71     // "LUT RAM". Doing so, however, burdens the
72     // timing of any
73     // logic to follow. By setting OPT_RE-
74     // GISTER_READS, we force
75     // all reads to be synchronous and not burdened by
76     // any logic.
77     // This tends to work with more hardware. If

5 // Project: WB2AXIPSP: bus bridges and other odds and ends
6 //
7 // Purpose: Bridge from an AXI4 slave to an AXI3 master
8 //
9 // The goal here is to not lose bus resolution, capacity
or capability,
10 // while bridging from AXI4 to AXI3. The biggest problem
with such
11 // a bridge is that we'll need to break large requests
(AxLEN>15) up
12 // into smaller packets. After that, everything should
work as normal
13 // with only minor modifications for AxCACHE.
14 //
15 // Opportunity:
16 // The cost of this core is very much determined by the

```

```

number of ID's
17 // supported. It should be possible, with little extra
cost or effort,
18 // to reduce the ID space herein. This should be a topic
for future
19 // exploration.
20 //
21 // Status:
22 // This core is an unverified first draft. It has past
neither formal
23 // nor simulation testing. Therefore, it is almost cer-
tain to have bugs
24 // within it. Use it at your own risk.

3 // Filename:    rtl/axi2axilite.v
4 // {{{
5 // Project:    WB2AXIPSP: bus bridges and other odds and ends
6 //
7 // Purpose:    Convert from AXI to AXI-lite with no perform-
ance loss.
8 //
9 // Performance: The goal of this converter is to convert from
AXI to AXI-lite
10 // while still maintaining the one-clock per
transaction speed
11 // of AXI. It currently achieves this goal. The design
needs very little
12 // configuration to be useful, but you might wish to res-
ize the FIFOs
13 // within depending upon the length of your slave's data
path. The current
14 // FIFO length, LGWFIPO=4, is sufficient to maintain full
speed. If the
15 // slave, however, can maintain full speed but requires a
longer
16 // processing cycle, then you may need longer FIFOs.
17 //
18 // The AXI specification does require an additional 2
clocks per
19 // transaction when using this core, so your latency will
go up.
20 //
21 // Related:    There's a related axidouple.v core in the same
repository as
22 // well. That can be used to convert the AXI pro-
tocol to something
23 // simpler (even simpler than AXI-lite), but it can also
do so for multiple
24 // downstream slaves at the same time.
