86
87 // If the receive path is set NOT to use an external differ-
88 // ential receiver:

```

```

82 // This block samples data purely from the usb_dp_i/usb_dn_i
pair.
83 // There is a chance that one of the signals in the pair
will appear to have
84 // changed to the new state while the other is still in the
old state. The
85 // following state machine detects transitions and waits an
extra sampling clock
86 // before decoding the state on the dp/dn pair. This trans-
ition period will

87 // only ever last for one clock as long as there is no noise on
the line.

88 // If there is enough noise on the line then the data may be
corrupted and the
89 // packet will fail the data integrity checks.
90
91 // If the receive path uses an external differential receiv-
er:
92 // This block uses the usb_d_i input to detect K and J sym-
bols.
93 // The individual signals of the differential pair must
still be connected
94 // to this block to detect SE0.
95 // Note that the spec warns in section 7.1.4.1:
96 // Both D+ and D- may temporarily be less than VIH (min)
during differential

97 // signal transitions. This period can be up to 14 ns (TFST)
for full-speed
98 // transitions and up to 210 ns (TLST) for low-speed trans-
itions. Logic in the
99 // receiver must ensure that this is not interpreted as an
SE0.
100 // Since the 48MHz sample clock is 20.833ns period we will
either miss this or
101 // sample it only once, so it will be covered by
line_state=DT and the next
102 // sample will not be SE0 unless this was a real SE0 trans-
ition
103 // Note: if it is a real SE0 the usb_d_i input could be do-
ing anything.

RISC-V 타이머

What. mtime/mtimecmp 레지스터와 타이머 인터럽트 생성.

Why it exists. 규격이 정한 최소 블록의 예다. RISC-V 권한 규격이 mtime 의 동작을 정의하므로, 구현 자유도가 거의 없다. 그래서 검증도 단순하다 — 규격대로인가만 본다.

학부 복습 · **EECS concepts.** 타이머/카운터 · 인터럽트 컨트롤러 · 64비트 카운터의 원자적 읽기 문제.

석사 수준 · **Practice note.** 64비트 카운터를 32비트 버스로 읽을 때의 찢김(**tearing**) 이 고전적 함정이다. 상위/하위를 따로 읽는 사이에 값이 넘어가면 엉뚱한 값이 나온다. 규격이 읽기 순서를 정하거나 새도우 레지스터를 둔다.

RISC-V 디버그 모듈

What. RISC-V Debug Spec 의 디버그 모듈. JTAG(DTM) → 디버그 모듈 → 코어 제어.

Why it exists. 칩이 안 뜰 때 볼 수 있는 유일한 창 이다. 이것이 없으면 브링업이 불가능하다. 그래서 디버그 모듈은 코어가 멈춰 있어도 동작해야 하고, 별도 클럭/리셋 도메인에 있는 경우가 많다.

학부 복습 · **EECS concepts.** JTAG TAP 상태기계(IEEE 1149.1) · 경계 스캔 · 디버그 트랜스포트 · 클럭 도메인 교차.

석사 수준 · **Practice note.** 디버그 경로가 보안 경계를 뚫는 통로 라는 점을 잊지 마라. 양산 칩은 수명주기 상태에 따라 디버그를 잠근다(OpenTitan 의 lc_ctrl 참고). 디버그와 보안의 충돌은 모든 보안칩의 설계 쟁점이다.

138 // In order to keep a RV_DM JTAG debug session alive during
NDM reset, we need to memorize the
139 // state of lc_hw_debug_en, since OTP/LC will be reset as
part of NDM reset (the only parts not
140 // reset are in the pwr/rst/clkmgrs, RV_DM and this strap
sampling module). We sample the life
141 // cycle signal state when the strap sampling pulse is as-
serted but the PWRMGR. This pulse is
142 // asserted once during boot (and not after an NDM reset).
143 //
144 // Note that we make sure to invalidate the sampled
lc_hw_debug_en whenever lc_check_byp_en or
145 // lc_escalate_en are not OFF. lc_escalate_en is asserted as
part of an escalation, and
146 // lc_check_byp_en is asserted whenever a life cycle trans-
ition is initiated (it causes the OTP
147 // controller to skip background checks on the life cycle
partition as it undergoes
148 // modification). This makes sure that the sampled value
here does not survive a life cycle
149 // transition.
150 //
151 // Finally, note that there is secondary gating on the RV_DM
and DFT TAPS that is always consuming
152 // live lc_hw_debug_en and lc_dft_en signals for added pro-
tection.

TL-UL 버스 구조

What. TileLink Uncached Lightweight 버스의 어댑터 · 소켓 · FIFO · 오류 응답.

Why it exists. 모든 주변장치를 같은 방식으로 붙이기 위해 서다. 버스를 통일하면 블록마다 인터페이스를 새로 만들 필요가 없고, 레지스터 생성기 · 검증 IP · 주소 디코더를 재사용할 수 있다. IP 재사용의 실질적 기반이 버스 표준화다.

학부 복습 · **EECS concepts.** 버스 프로토콜 · 핸드셰이크 · 주소 디코딩 · 중재 · 파이프라이닝과 처리량.

석사 수준 · **Practice note.** 버스 어댑터는 ‘공짜’가 아니다. 지연이 붙고 면적을 먹는다. 작은 블록에서는 어댑터가 본체보다 클 수도 있다. IP 자원 보고에 어댑터 포함/제외를 명시하라.

5 // tlul_adapter (Host adapter) converts basic req/grant/rvalid
into TL-UL interface. If
6 // MAX_REQS == 1 it is purely combinational logic. If MAX_REQS > 1
flops are required.
7 //
8 // The host driving the adapter is responsible for ensuring it
doesn't have more requests in flight
9 // than the specified MAX_REQS.
10 //
11 // The outgoing address is always word aligned. The access
size is always the word size (as
12 // specified by TL_DW). For write accesses that occupy all
lanes the operation is PutFullData,
13 // otherwise it is PutPartialData, mask is generated from
be_i. For reads all lanes are enabled as
14 // required by TL-UL (every bit in mask set).
15 //
16 // When MAX_REQS > 1 tlul_adapter_host does not do anything to
order responses from the TL-UL
17 // interface which could return them out of order. It is the
host's responsibility to either only
18 // have outstanding requests to an address space it knows will
return responses in order or to not
19 // care about out of order responses (note that if read data
is returned out of order there is no
20 // way to determine this).

7 // Tile-Link UL to register interface adapter
8 //
9 // This module acts as a device, addressed through the TL-UL
bus. It receives Get, PutPartialData
10 // and PutFullData messages on the A channel. These are read
or write requests, which are passed to
11 // the register interface on the same cycle. The response from
the register interface is sent back
12 // to the host as a message on the D channel on the next
cycle.
13 //
14 // A module instance performs several checks on A-channel mes-
sages and only forwards a request to
15 // the register interface if they all pass. These checks are:
16 //
17 // - A_OPCODE must be Get, PutPartialData or PutFullData.
18 //
19 // - A_SIZE must be 0, 1 or 2 (giving a 1-, 2- or 4-byte op-
eration, respectively).
20 //
21 // - A_ADDRESS must be naturally aligned for the operation
byte width signaled in A_SIZE.
22 //
23 // - A_MASK must only be true for active byte-lanes. The pos-
ition of the first of these active
24 // lanes is calculated from the address, modulo the width
of the TL-UL data bus.
25 //
26 // - If the A_USER.INSTR_TYPE value is MuBi4True, A_OPCODE
must be Get.
27 //
28 // - Either the A_USER.INSTR_TYPE value must be a value other
than MuBi4True or the en_ifetch_i
29 // port must be MuBi4True.
30 //
31 // - If the CmdIntgCheck parameter is true then the command
integrity check must pass.
32 //
33 //
34 // ** Parameters
35 //
36 // CmdIntgCheck: If this parameter is true then there is a
"command integrity check". This uses a
37 // tlul_cmd_intg_chk instance to compare integ-
rity checksums from requests on the A
38 // channel. If the integrity checksums don't
match, the adapter doesn't pass the
39 // request to the register interface through
re_o/we_o and the response on the D
40 // channel will then have its D_ERROR flag set.
41 //
42 // EnableRspIntgGen: OpenTitan sends response integrity with
messages on the TL-UL bus. If this
43 // parameter is true, the module will per-
form calculations to send a correct
44 // integrity value in the response's
A_USER.RSP_INTG field.
45 //
46 // EnableDataIntgGen: This parameter is analogous to EnableR-
spIntgGen but controls whether the
47 // module performs calculations to send a

```

```

correct integrity value in the
48 //           response's A_USER.DATA_INTG field.
49 //
50 // RegAw: The number of bits used for addresses in the re-
gister interface. Higher bits of the
51 //           A_ADDRESS field in an A channel message are ignored.
52 //
53 // RegDw: The number of bits used for data words in the re-
gister interface. This is assumed to match
54 //           the data width of the TL-UL bus (see the Matched-
Width_A assertion).
55 //
56 // AccessLatency: This adapter always returns TileLink re-
sponses after one cycle, but this parameter

57 //           allows it to handle different timings on the
register interface. If AccessLatency
58 //           is zero then the adapter expects a combinat-
orial response on the register
59 //           interface and flops the result to break
paths and add a cycle delay. If
60 //           AccessLatency is one then the adapter ex-
pects a response on the register interface

61 //           in the cycle after the re_o/we_o signal goes
high, but then forwards it
62 //           combinatorially to the TileLink interface.
Only values 0 and 1 are allowed for
63 //           this parameter.
64 //
65 //
66 // ** Ports
67 //
68 // clk_i/rst_ni: Clock and reset.
69 // tl_i/tl_o: Connections to the TL-UL bus.
70 // en_ifetch_i: This mubi4_t port controls whether to allow
read requests from Get messages whose

71 //           A_USER.INSTR_TYPE is MuBi4True (considered to be
processor "fetch" requests).
72 // intg_error_o: This port is high when the adapter has detec-
ted a command integrity error. That can
73 //           only happen if the CmdIntgCheck parameter is
set.

74 // re_o/we_o: The read-enable and write-enable ports in the
register interface.
75 // addr_o: The address to read or write through the re-
gister interface.
76 // wdata_o: The value to write through the register in-
terface if we_o is true.
77 // be_o: A byte-enable signal, which is true for each
byte-lane where the TL-UL operation's
78 // mask is true.
79 // busy_i: If this input is high then the A channel in-
terface is stalled (by dropping
80 //           A_READY), which means that the adapter will
not accept any new operations.
81 // rdata_i: Read data being returned for a read request
through the register interface.

82 // error_i: An error flag in the register interface. This
signals that an error has been seen,
83 //           which can be seen in the D channel response
by D_ERROR being high. The D_DATA
84 //           response is also set to '1, squashing any
data that might have been returned
85 //           through rdata_i.
86 //
87 // ICEBOX(#15822): Note that due to some modules with special
needs (like the vendored-in RV_DM),
88 //           this module has been extended so that it
supports use cases outside of the
89 //           generated reg_top module. This makes this
adapter and its parameterization
90 //           options a bit heavy.
91 //
92 //           We should in the future come back to this
and refactor / align the module and its
93 //           parameterization needs.
94 //

9 Tile-Link UL response integrity generator
10

11 This generates integrity bits that get stored in the rsp_intg
and data_intg fields of tl_o.d_user.
12
13 If EnableRspIntgGen is true then the rsp_intg field is gener-
ated from the opcode, d_size and
14 d_error fields of the response (extracted with tlul_pkg::ex-
tract_d2h_rsp_intg). If it is false then
15 the rsp_intg field either comes from the same field in the
tl_i input (if UserInIsZero is false) or
16 is wired to zero (if UserInIsZero is true).
17
18 If EnableDataIntgGen is true then the data_intg field is gen-
erated from the d_data field of the
19 response. If it is false then the rsp_intg field either comes
from the same field in the tl_i input
20 (if UserInIsZero is false) or is wired to zero (if UserIn-
IsZero is true).

SRAM 컨트롤러(스크램블)

What. SRAM 접근을 주소/데이터 스크램블하고 ECC 를 붙이는 컨트롤러.

Why it exists. 메모리에 담긴 비밀이 물리적으로 읽히는 것을 막기 위해서다. 칩을 열어 SRAM 셀을 직접 읽는 공격이 실재하므로, 저장할 때 주소와 데이터를 섞는다. 동시에 소프트 에러(우주선/알파입자)를 잡기 위해 ECC 를 건다.

학부 복습 · **EECS concepts.** 경량 블록암호(PRINCE 등) · 오류정정부호(SECDED 해밍) · 소프트 에러율(SER)과 FIT 단위.

석사 수준 · **Practice note.** ECC 를 붙이면 지연이 1사이클 늘어난다. 파이프라인이 그것을 흡수할 수 있는지 초기에 확인하라. 나중에 발견하면 타이밍 재설계다.

OTP 컨트롤러

What. 일회성 프로그래머블 메모리의 컨트롤러.

Why it exists. 지울 수 없는 저장소가 필요하다 — 칩 고유 키, 수명주기 상태, 보정값. 한 번 쓰면 못 되돌리므로 쓰기 절차가 극도로 보수적이다.

학부 복습 · **EECS concepts.** 비휘발성 메모리 물리(eFuse, 안티퓨즈) · 오류정정 · 먹등 쓰기.

석사 수준 · **Practice note.** OTP 관련 버그는 수정 불가능한 칩을 만든다. 이 블록의 검증은 다른 어떤 블록보다 보수적으로 한다.

키 관리자

What. 루트 키에서 용도별 파생 키를 만들고 수명주기에 따라 접근을 통제하는 블록.

Why it exists. 키를 소프트웨어에 절대 노출하지 않기 위해 서다. 소프트웨어는 “이 용도의 키로 서명해 달라”고 요청할 뿐, 키 값을 못 본다. 키는 하드웨어 경로로만 암호 엔진에 전달된다.

학부 복습 · **EECS concepts.** 키 파생 함수(KDF) · 신뢰의 사슬(chain of trust) · 최소 권한 원칙 · 하드웨어 격리.

석사 수준 · **Practice note.** ‘하드웨어 키 경로’가 실제로 격리됐는지는 **RTL** 을 읽어야 한다. 디버그 경로, 스캔 체인, 테스트 모드로 새는 경로가 없는지가 보안 감사의 핵심 항목이다. 스캔 체인은 모든 플립플롭을 읽을 수 있다 — 그래서 양산 칩은 스캔을 잠근다.

수명주기 컨트롤러

What. 칩의 수명 단계(RAW → TEST → DEV → PROD → RMA)를 관리하고 단계별로 기능을 열고 닫는 블록.

Why it exists. 공장에서는 열려 있어야 하고 현장에서는 닫혀 있어야 하는 기능 이 있기 때문이다. 테스트 모드·디버그·키 주입이 그렇다. 단계 전이는 되돌릴 수 없고, 각 전이는 토큰(비밀값)으로 인증된다.

학부 복습 · **EECS concepts.** 상태기계 · 접근 제어 · 비가역 전이 · 안전한 기본값(fail-closed).

석사 수준 · **Practice note.** 이 블록은 ‘제품 전략’이 실리콘에 박힌 것 이다. 어떤 기능을 언제 잠글지는 엔지니어링이 아니라 사업 결정이고, 그것을 RTL 로 옮기는 것이 이 블록이다. 요구사항 변경이 가장 잦은 블록이기도 하다.

OpenTitan 기본 셀 라이브러리

What. 동기화기 · FIFO · 카운터 · LFSR · 아비터 · 패리티/ECC · 보안 프리미티브 (이중화 레지스터, 상보 신호) 모음.

Why it exists. 같은 것을 두 번 만들지 않기 위해서 이고, 더 중요하게는 미묘한 것을 한 번만 제대로 만들기 위해서다. 동기화기를 블록마다 각자 쓰면 그중 하나는 틀린다. 라이브러리에 두고 검증하면 한 번만 맞으면 된다.

학부 복습 · **EECS concepts.** 메타스테이빌리티와 MTBF · 그레이 부호 · LFSR 과 원시다항식 · 라운드로빈 중재의 공정성.

석사 수준 · **Practice note.** 1인 디자인 하우스가 가장 먼저 만들어야 할 것이 이 라이브러리다. 블록을 팔려면 그 안의 기본 셀들이 이미 검증돼 있어야 한다. OpenTitan 의 `prim_` 접두 모듈을 읽고 자기 것을 만들어라 — 라이선스 (Apache-2.0)가 허용한다.

4 //
5 // The alert receiver primitive decodes alerts that have been
  differentially
6 // encoded and transmitted via a handshake protocol on
  alert_p/n and
7 // ack_p/n. In case an alert handshake is initiated, the out-
  put alert_o will
8 // immediately be asserted (even before completion of the
  handshake).
9 //
10 // In case the differential input is not correctly encoded,
  this module will
11 // raise an error by asserting integ_fail_o.
12 //
13 // Further, the module supports ping testing of the alert diff
  pair. In order to
14 // initiate a ping test, ping_req_i shall be set to 1'b1 until
  ping_ok_o is
15 // asserted for one cycle. The signal may be de-asserted (e.g.
  after a long)
16 // timeout period. However note that all ping responses that
  come in after
17 // deasserting ping_req_i will be treated as native alerts.
18 //
19 // The protocol works in both asynchronous and synchronous
  cases. In the
20 // asynchronous case, the parameter AsyncOn must be set to
  1'b1 in order to
21 // instantiate additional synchronization logic. Further, it
  must be ensured
22 // that the timing skew between all diff pairs is smaller than
  the shortest
23 // clock period of the involved clocks.
24 //
25 // Note that in case of synchronous operation, alerts on the
  diffpair are
26 // decoded combinatorially and forwarded on alert_o within the
  same cycle.
27 //
28 // See also: prim_alert_sender, prim_diff_decode,
  alert_handler

4 //
5 // The alert sender primitive module differentially encodes
and transmits an
6 // alert signal to the prim_alert_receiver module. An alert
will be signalled
7 // by a full handshake on alert_p/n and ack_p/n. The
alert_req_i signal may
8 // be continuously asserted, in which case the alert sig-
nalling handshake
9 // will be repeatedly initiated.
10 //
11 // The alert_req_i signal may also be used as part of req/ack.
The parent module
12 // can keep alert_req_i asserted until it has been ack'd
(transferred to the alert
13 // receiver). The parent module is not required to use this.
14 //
15 // In case the alert sender parameter IsFatal is set to 1, an
incoming alert
16 // alert_req_i is latched in a local register until the next
reset, causing the
17 // alert sender to behave as if alert_req_i were continuously
asserted.
18 // The alert_state_o output reflects the state of this intern-
al latching register.
19 //
20 // The alert sender also exposes an alert test input, which
can be used to trigger
21 // single alert handshakes. This input behaves exactly the
same way as the
22 // alert_req_i input with IsFatal set to 0. Test alerts do not
cause alert_ack_o
23 // to be asserted, nor are they latched until reset (regard-
less of the value of the
24 // IsFatal parameter).
25 //
26 // Further, this module supports in-band ping testing, which
means that a level
27 // change on the ping_p/n diff pair will result in a full-
handshake response
28 // on alert_p/n and ack_p/n.
29 //
30 // The protocol works in both asynchronous and synchronous
cases. In the
31 // asynchronous case, the parameter AsyncOn must be set to
1'b1 in order to
32 // instantiate additional synchronization logic. Further, it
must be ensured
33 // that the timing skew between all diff pairs is smaller than
the shortest
34 // clock period of the involved clocks.
35 //
36 // Incorrectly encoded diff inputs can be detected and will be
signalled
37 // to the receiver by placing an inconsistent diff value on
the differential
38 // output (and continuously toggling it).
39 //

13 //
14 // This is a tree implementation of a round robin arbiter. It
15 has the same behavior as the PPC
16 // implementation in prim_arbiter_ppc, and also uses a prefix
17 summing approach to determine the next
18 // request to be granted. The main difference with respect to
19 the PPC arbiter is that the leading 1
20 // detection and the prefix summation are performed with a
21 binary tree instead of a sequential loop.
22 // Also, if the data port is enabled, the data is muxed based
23 on the local arbitration decisions at
24
25 // each node of the arbiter tree. This means that the data can
26 propagate through the tree
27 // simultaneously with the requests, instead of waiting for
28 the arbitration to determine the winner
29 // index first. As a result, this design has a shorter critic-
30 al path than other implementations,
31 // leading to better overall timing.
32
33 // Note that the currently winning request is held if the data
34 sink is not ready. This behavior is
35 // required by some interconnect protocols (AXI, TL). The mod-
36 ule contains an assertion that checks
37 // this behavior.

5 // This is a wrapper module that instantiates two prim_arbit-
er_tree modules.
6 // The reason for two is similar to modules such as
prim_count/prim_lfsr where
7 // we use spatial redundancy to ensure the arbitration results are
not altered.
8 //
9 // Note there are limits to this check, as the inputs to the
duplicated arbiter
10 // is still a single lane. So an upstream attack can defeat
this module. The
11 // duplication merely protects against attacks directly on the
arbiter.

55 // The basic helper macros are actually defined in "implement-
ation headers". The macros should do
56 // the same thing in each case (except for the dummy flavour),
but in a way that the respective
57 // tools support.
58 //
59 // If the tool supports assertions in some form, we also
define INC_ASSERT (which can be used to
60 // hide signal definitions that are only used for assertions).
61 //
62 // The list of basic macros supported is:
63 //
64 // ASSERT_I: Immediate assertion. Note that immediate as-
sertions are sensitive to simulation
65 // glitches.
66 //
67 // ASSERT_INIT: Assertion in initial block. Can be used for
things like parameter checking.
68 //
69 // ASSERT_INIT_NET: Assertion in initial block. Can be used
for initial value of a net.
70 //
71 // ASSERT_FINAL: Assertion in final block. Can be used for
things like queues being empty at end of
72 // sim, all credits returned at end of sim,
state machines in idle at end of sim.

```

```

73 //
74 // ASSERT_AT_RESET: Assertion just before reset. Can be used
to check sum-like properties that get
75 // cleared at reset.
76 // Note that unless your simulation ends
with a reset, the property does not get
77 // checked at end of simulation; use AS-
SERT_AT_RESET_AND_FINAL if the property
78 // should also get checked at end of simula-
tion.
79 //

80 // ASSERT_AT_RESET_AND_FINAL: Assertion just before reset and in
final block. Can be used to check
81 // sum-like properties before
every reset and at the end of simulation.
82 //
83 // ASSERT: Assert a concurrent property directly. It
can be called as a module (or
84 // interface) body item.
85 //
86 // Note: We use (__rst != '0') in the disable
iff statements instead of (__rst ==

87 // '1). This properly disables the assertion in
cases when reset is X at the
88 // beginning of a simulation. For that case,
(reset == '1) does not disable the
89 // assertion.
90 //
91 // ASSERT_NEVER: Assert a concurrent property NEVER happens
92 //
93 // ASSERT_KNOWN: Assert that signal has a known value (each
bit is either '0' or '1') after reset.
94 // It can be called as a module (or interface)
body item.
95 //
96 // COVER: Cover a concurrent property
97 //
98 // ASSUME: Assume a concurrent property
99 //
100 // ASSUME_I: Assume an immediate property
101 //

5 // This module should be instantiated within flops of CDC syn-
  chronization primitives,
6 // and allows DV to model real CDC delays within simulations,
  especially useful at the chip level
7 // or in IPs that communicate across clock domains.
8 //
9 // The instrumentation is very simple: when this is enabled
  the input into the first
10 // synchronizer flop has a mux where the select is randomly
  set. One of the mux inputs is the input
11 // of this module, and the other is the output of the first
  flop: selecting the latter models the
12 // effect of the first flop missing the input transition.
13 //
14 // Notice the delay should cause the input to be skipped by at
  most a single cycle. As a perhaps
15 // unnecessary precaution, the select will only be allowed to
  be random when the input changes.

5 // Hardened counter primitive:
6 //
7 // This internally uses a cross counter scheme with primary
and a secondary counter, where the
8 // secondary counter counts in reverse direction. The sum of
both counters must remain constant and
9 // equal to 2**Width-1 or otherwise an err_o will be asserted.
10 //
11 // This counter supports a generic clear / set / increment /
decrement interface:
12 //
13 // clr_i: This clears the primary counter to ResetValue and
adjusts the secondary counter to match
14 // (i.e. 2**Width-1-ResetValue). Clear has priority
over set, increment and decrement.
15 // set_i: This sets the primary counter to set_cnt_i and ad-
justs the secondary counter to match
16 // (i.e. 2**Width-1-set_cnt_i). Set has priority over
increment and decrement.
17 // incr_en_i: Increments the primary counter by step_i, and
decrements the secondary by step_i.
18 // decr_en_i: Decrements the primary counter by step_i, and
increments the secondary by step_i.
19 // commit_i: Counter changes only take effect when `commit_i`
is set. This does not effect the
20 // `cnt_after_commit_o` output which gives the next
counter state if the change is
21 // committed.
22 //
23 // Note that if both incr_en_i and decr_en_i are asserted at
the same time, the counter remains
24 // unchanged. The counter is also protected against under- and
overflows.

5 // CRC32 calculator
6 //
7 // This module takes in n-bits data words (n defined by Byte-
PerWord parameter) and updates an
8 // internally stored CRC with each valid data word. The poly-
nomial used is the standard CRC32 IEEE
9 // one. An interface is provided to set the internal CRC to an ar-
bitrary value. The output CRC is an
10 // inverted version of the internally stored CRC and the input
CRC is inverted before being stored.
11 // This is done so results match existing widely used software
libraries (e.g. the crc32
12 // functionality available in Python). Note that a initial CRC of
0x0 (corresponding to an internal
13 // CRC of 0xffffffff) must be used to match results generated
elsewhere.

5 // This module decodes a differentially encoded signal and de-
fects
6 // incorrectly encoded differential states.
7 //
8 // In case the differential pair crosses an asynchronous
boundary, it has
9 // to be re-synchronized to the local clock. This can be
achieved by
10 // setting the AsyncOn parameter to 1'b1. In that case, two
additional
11 // input registers are added (to counteract metastability),
and
12 // a pattern detector is instantiated that detects skewed
level changes on
13 // the differential pair (i.e., when level changes on the diff
pair are
14 // sampled one cycle apart due to a timing skew between the
two wires).
15 //
16 // See also: prim_alert_sender, prim_alert_receiver,
alert_handler

19 // HMAC-SHA-512/384 core with SCA countermeasures.
20 // Single SHA-512 masked core architecture for area optimiza-
tion.
21 //
22 // Commands:
23 //   init_cmd - SHA-init with (K xor ipad), then SHA-next
with first
24 //               message block. If issued together with
last_cmd,
25 //               continues directly to inner-digest capture,
OPAD, and
26 //               HMAC finalization.
27 //   next_cmd - SHA-next with one intermediate message block.
28 //   last_cmd - SHA-next with the final message block, cap-
tures the
29 //               inner digest, then SHA-init with (K xor opad)
and
30 //               SHA-next with {inner_digest, FINAL_PAD} to
produce
31 //               the HMAC tag.

18 // -----
19 // Elliptic Curve Cryptography (ECC) digital signature al-
gorithm (DSA)
20 // controller to support deterministic ECDSA based on RFC
6979.
21 // The dsa architecture includes several countermeasures to
be protected
22 // against a subset of side-channel analysis (SCA) attacks.
23 //
24 // The architecture includes:
25 // 1) ecc_dsa_sequencer: including the required sequence to
perform
26 // keygen, signing, and verifying.
27 // 2) ecc_arith_unit: the arithmetic unit to perform point
multiplication
28 // and other required operations
29 // 3) hmac_drbg: the hmac384 drbg component to support RFC
6979
30 // 4) ecc_scalar_blinding: the SCA countermeasure to random-
ized scalar
31 // to avoid information leakage.
32 //
33 // The embedded countermeasures are:
34 // - point randomization:
35 // Randomized Projective Coordinates countermeasure based on
section 5.3
36 // "Resistance against Differential Power Analysis for
Elliptic Curve

```

```

37 // Cryptosystems" in CHES 1999 by Coron, J.
38 // This countermeasure uses a random value "lambda" in
point multiplication
39 // (Q = k * P) in keygen/signing to randomize base point
P = (X, Y, 1)
40 // as follows:
41 // P = (X * Lambda, Y * lambda, Lambda)
42 // - scalar blinding:
43 // Scalar blinding countermeasure based on section 5.1
44 // "Resistance against Differential Power Analysis for
Elliptic Curve
45 // Cryptosystems" in CHES 1999 by Coron, J.
46 // This countermeasure uses a random value "r" in the
point multiplication
47 // (Q = k * P) in keygen/signing to randomize scalar k as
follows:
48 // k = k + r*group_order
49 // - masking signature:
50 // Masking sign countermeasure uses a random value "d" in
the signing
51 // operation to generate signature proof s = (privkey * r +
h)*k_inv
52 // as follows:
53 // s = [((privkey - d) * r + (h - d)) * k_inv] + [(d * r
+ d) * k_inv]

17 // ecc_dsa_sequencer.sv
18 // -----
19 // This module contains the sequence of ECC operation. it in-
cludes 4 sequences
20 // of operation:

21 // 1) reset sequence: After reset, the core will initilze the
data memory based
22 // on the first lines of sequencer. Then,
it will stay on NOP
23 // line until getting the command.
24 // 2) keygen sequence: After getting the keygen command, it
will generate and
25 // randomize privkey and feed it into the
pm core and return
26 // key pairs of (privkey, pubkey)

27 // 3) sign sequence: After getting the sign command, it will
generate and
28 // randomize nonce and feed it into the pm
core and return
29 // the signature (R,
S).
30 // 4) verify sequence: After getting the verify command, it
will feed the signature
31 // into the pm core and return the com-
puted verify_R.
32 //
33 //

19 // interface with hmac_drbg component to generate the required
20 // values:
21 // 1) in keygen mode:
22 // 1.1. generate lambda from IV for point randomization
23 // 1.2. generate scalar_rnd from IV for scalar blinding

```

```

SCA countermeasure
23 // 1.3. generate privkey from seed and nonce for key gen-
24 // 2) in sign mode:
25 // 2.1. generate lambda from IV for point randomization
SCA countermeasure
26 // 2.2. generate scalar_rnd from IV for scalar blinding
SCA countermeasure
27 // 2.3. generate masking_rnd from IV for masking signa-
28 // 2.4. generate k from privkey and hashed_msg for sign-
29 //
30 // To generate random values using IV, the hmac_drbg is con-
31 // tinued by triggering
32 // next command (instead of init).
33 //
34 // - INIT: Instantiates HMAC-DRBG with entropy,
35 // nonce, (personalization string is empty).
36 // Then, it calls
37 // HMAC_DRBG_Generate_algorithm (additional input string is empty)
38 // to generate a 384-bit random value while
39 // it's in (0, prime) range.
40 // if the random value is zero or >= prime,
41 // it is rejected and a new random value
42 // is generated by calling
43 // HMAC_DRBG_Generate_algorithm.
44 // There is NO RESEED process.
45 // - NEXT: it calls HMAC_DRBG_Generate_algorithm (ad-
46 // ditional input string is empty)
47 // to generate a 384-bit random value while
48 // it's in (0, prime) range.
49 // if the random value is zero or >= prime,
50 // it is rejected and a new random value
51 // is generated by calling
52 // HMAC_DRBG_Generate_algorithm.
53 // There is NO RESEED process.

16 // Module:
17 // ecc_montgomerymultiplier.sv
18 //
19 // Montgomery Multiplier based on
20 // Optimized Algorithms and Architectures for Montgomery Mul-
tiplication
21 // for Post-quantum Cryptography by Rami Elkhatab et. al.
22 //
23 // Description:
24 // The module produces a Montgomery product of input op-
erands with the following constraints:
25 // Input operands must be less than n_i, i.e. opa_i <
n_i and opb_i < n_i.
26 // RADIX > 2
27 // R = 2^((ceil($bits(n_i) / RADIX) + 1) * RADIX)
28 // R > n_i.
29 // (1) T = opa_i * opb_i < n_i * n_i = n_i^2
30 // (2) p_internal = (T + (T*n_prime mod R) * n_i) / R
31 // (3) p_subtracted_internal = p_internal - n_i
32 // (4) p_o = (p_internal >= ni)? p_subtracted_internal :
p_internal
33 // From (1) and (2) given R > n_i, and opa_i, opb_i <
n_i:
34 // p_internal < (n_i^2 + R * n_i) / R = n_i + n_i^2 / R
< n_i + n_i^2 / n_i = n_i + n_i = 2*n_i
35 // From (3) and (4):
36 // p_subtracted_internal < 2*n_i - n_i = n_i
37 // p_o < n_i

21 // The architecture includes ecc_pm_sequencer including the
22 // required
23 // sequence to perform:
24 // - point multiplication (pm) based on Montgomery ladder
25 // and Fermat's little
26 // theorem (FLT) inversion
27 // - Montgomery ladder initialization with base point G or
28 // public key PK in
29 // keygen, signing, or verifying operations.
30 // - Montgomery ladder steps: including the iterative point
31 // addition (PA)

```

```

28 // and point doubling (PD) operations in Montgomery domain
29 // using projective
30 // coordinates. The number of iteration is equal to REG_S-
31 // IZE of scalar in
32 //
33 // unprotected point multiplication, and REG_SIZE+RND_SIZE of
34 // scalar in the
35 // SCA protected operation.
36 // - Modular Inversion (mod p, mod q) is based on Fermat's
37 // little theorem (FLT)
38 // inversion.
39 // - Conversion from projective coordinates in Montgomery
40 // domain (X,Y,Z) to
41 // affine coordinates in the normal domain (x,y).
42 // - Modular arithmetic operations such as (h + r*privKey)
43 // in signing
44 // or (h*s_inv) and (r*s_inv) in verifying

387
388 // SEC_CM: CTRL.SPARSE
389 // We use sparse encodings for various critical signals and
must ensure that:
391 // 1. The synthesis tool doesn't optimize away the sparse
encoding.
392 // 2. The sparsely encoded signal is always valid. More pre-
cisely, an alert or SVA is triggered
393 //    if a sparse signal takes on an invalid value.
394 // 3. The alert signal remains asserted until reset even if
the sparse signal becomes valid again
395 //    This is achieved by driving the control FSM into the
terminal error state whenever any
396 //    sparsely encoded signal becomes invalid.
397 //
398 // If any sparsely encoded signal becomes invalid, the
cipher core further immediately de-asserts
399 // the out_valid_o signal to prevent any data from being re-
leased.

6 // AES cipher core control FSM
7 //
8 // This module contains the AES cipher core control FSM oper-
9 // ating on and producing the negated
10 // values of important control signals. This is achieved by:
11 // - instantiating the regular AES cipher core control FSM op-
12 // erating on and producing the positive
13 // values of these signals, and
14 // - inverting these signals between the regular FSM and the
15 // caliptra_prim_buf synthesis barriers.
16 // Synthesis tools will then push the inverters into the actu-
17 // al FSM.
