386   ///////////////////////////////////////////////////
387   // SEC_CM: CTRL.SPARSE
388   // We use sparse encodings for various critical signals and
must ensure that:
391   // 1. The synthesis tool doesn't optimize away the sparse
encoding.
392   // 2. The sparsely encoded signal is always valid. More pre-
cisely, an alert or SVA is triggered
393   // if a sparse signal takes on an invalid value.
394   // 3. The alert signal remains asserted until reset even if
the sparse signal becomes valid again
395   // This is achieved by driving the control FSM into the
terminal error state whenever any
396   // sparsely encoded signal becomes invalid.
397   //
398   // If any sparsely encoded signal becomes invalid, the
cipher core further immediately de-asserts
399   // the out_valid_o signal to prevent any data from being re-
leased.

5 // AES cipher core control FSM

```

```

6 //
7 // This module contains the AES cipher core control FSM oper-
ating on and producing the negated
8 // values of important control signals. This is achieved by:
9 // - instantiating the regular AES cipher core control FSM op-
erating on and producing the positive
10 // values of these signals, and
11 // - inverting these signals between the regular FSM and the
prim_buf synthesis barriers.
12 // Synthesis tools will then push the inverters into the actu-
al FSM.

5 // AES cipher core implementation
6 //
7 // This module contains the AES cipher core including, state
register, full key and decryption key
8 // registers as well as key expand module and control unit.
9 //
10 //
11 // Masking
12 // -----
13 //
14 // If the parameter "Masking" is set to one, first-order mask-
ing is applied to the entire
15 // cipher core including key expand module. For details, see
Rivain et al., "Provably secure
16 // higher-order masking of AES" available at https://
eprint.iacr.org/2010/441.pdf .
17 //
18 //
19 // Details on the data formats
20 // -----
21 //
22 // This implementation uses 4-dimensional SystemVerilog arrays to
represent the AES state:
23 //
24 //     logic [3:0][3:0][7:0] state_q [NumShares];
25 //
26 // The fourth dimension (unpacked) corresponds to the differ-

```

ent shares. The first element holds the
27 // (masked) data share whereas the other elements hold the
masks (masked implementation only).

28 // The three packed dimensions correspond to the 128-bit state
matrix per share. This
29 // implementation uses the same encoding as the Advanced En-
cryption Standard (AES) FIPS Publication
30 // 197 available at https://www.nist.gov/publications/ad-
vanced-encryption-standard-aes (see Section
31 // 3.4). An input sequence of 16 bytes (128-bit, left most
byte is the first one)

```

32 //
33 //     b0 b1 b2 b3 b4 b5 b6 b7 b8 b9 b10 b11 b12 b13 b14 b15
34 //
35 // is mapped to the state matrix as
36 //
37 //     [ b0 b4 b8 b12 ]
38 //     [ b1 b5 b9 b13 ]
39 //     [ b2 b6 b10 b14 ]
40 //     [ b3 b7 b11 b15 ] .
41 //
42 // This is mapped to three packed dimensions of SystemVerilog
array as follows:
43 // - The first dimension corresponds to the rows. Thus,
state_q[0] gives
44 // - The first row of the state matrix [ b0 b4 b8
b12 ], or
45 // - A 32-bit packed SystemVerilog array 32h'{ b12, b8, b4,
b0 }.
46 //
47 // - The second dimension corresponds to the columns. To ac-
cess complete columns, the state matrix
48 // must be transposed first. Thus state_transposed =
aes_pkg::aes_transpose(state_q) and then
49 // state_transposed[1] gives
50 // - The second column of the state matrix [ b4 b5 b6
b7 ], or
51 // - A 32-bit packed SystemVerilog array 32h'{ b7, b6, b5,
b4 }.
52 //
53 // - The third dimension corresponds to the bytes.
54 //
55 // Note that the CSRs are little-endian. The input sequence
above is provided to 32-bit DATA_IN_0 -
56 // DATA_IN_3 registers as
57 //
58 //     MSB                                LSB
59 // - DATA_IN_0 32h'{ b3 , b2 , b1 , b0 }
60 // - DATA_IN_1 32h'{ b7 , b6 , b4 , b4 }
61 // - DATA_IN_2 32h'{ b11, b10, b9 , b8 }
62 // - DATA_IN_3 32h'{ b15, b14, b13, b12 } .
63 //
64 // The input state can thus be obtained by transposing the
content of the DATA_IN_0 - DATA_IN_3
65 // registers.

```

66 // Similarly, the implementation uses a 3-dimensional array to
represent the AES keys:

```

67 //
68 //     logic [7:0][31:0] key_full_q [NumShares]
69 //

```

70 // The third dimension (unpacked) corresponds to the different
shares. The first element holds the
71 // (masked) key share whereas the other elements hold the
masks (masked implementation only).

72 // The two packed dimensions correspond to the 256-bit key per
share. This implementation uses

73 // the same encoding as the Advanced Encryption Standard (AES)
FIPS Publication
74 // 197 available at https://www.nist.gov/publications/ad-
vanced-encryption-standard-aes .

75 //
76 // The first packed dimension corresponds to the 8 key words.
The second packed dimension
77 // corresponds to the 32 bits per key word. A key sequence of
32 bytes (256-bit, left most byte is
78 // the first one)

```

79 //
80 //     b0 b1 b2 b3 b4 b5 b6 b7 b8 b9 b10 b11 b12 b13 b14
b15 ... .. b28 b29 b30 b31
81 //
82 // is mapped to the key words and registers (little-endian) as
83 //
84 //     MSB                                LSB
85 // - KEY_SHARE0_0 32h'{ b3 , b2 , b1 , b0 }
86 // - KEY_SHARE0_1 32h'{ b7 , b6 , b4 , b4 }
87 // - KEY_SHARE0_2 32h'{ b11, b10, b9 , b8 }
88 // - KEY_SHARE0_3 32h'{ b15, b14, b13, b12 }
89 // - KEY_SHARE0_4 32h'{ . . . . }
90 // - KEY_SHARE0_5 32h'{ . . . . }
91 // - KEY_SHARE0_6 32h'{ . . . . }
92 // - KEY_SHARE0_7 32h'{ b31, b30, b29, b28 } .

OpenTitan HMAC-SHA256

What this is. HMAC and SHA-256 combined in one block with a FIFO and a register interface.

Why it exists. Because the streaming interface, not the hash, is most of the work. Message lengths are arbitrary and software delivers fragments, so the hardware must handle buffering, byte alignment, final-block padding, and suspend/resume.

Undergraduate review · EECS concepts. HMAC's ipad/opad construction; stream processing; backpressure; byte-enable handling.

Graduate · Practice note. In most blocks the interface exceeds 70% of the code. Schedules that assume the algorithm is the work are systematically optimistic.

445 // The FIFO empty interrupt is **not useful** for software
if:
446 // - The HMAC block is running in HMAC mode and performing
the second round of computing the
447 // final hash of the outer key as well as the result of
the first round using the inner key.
448 // - The FIFO is then managed entirely by the hardware.
449 // - The FIFO is currently not writeable by software.
450 // - Software has already written the Process command. The
HMAC block will now empty the
451 // FIFO and load its content into the SHA2 core, add the
padding and then perform
452 // the final hashing operation. Software cannot append the
message further.
453 // - Software has written the Stop command. The HMAC block
will not wait for further input from
454 // software after finishing the current block.
455 //
456 // The FIFO empty interrupt can be **useful** for software
in particular if:
457 // - The FIFO was completely full previously. However, un-
less the HMAC block is currently
458 // processing a block, it always empties the message FIFO
faster than software can fill it up,
459 // meaning the message FIFO is empty most of the time.

OpenTitan KMAC (Keccak/SHA-3)

What this is. SHA-3 family and KMAC built on the Keccak-f[1600] permutation.

Why it exists. Because its construction differs fundamentally from SHA-2. It is a sponge, not a Merkle–Damgård chain: a large state is stirred by a permutation while data is absorbed and squeezed. In hardware this becomes a 1600-bit register and very wide combinational logic.

Undergraduate review · EECS concepts. Sponge constructions; permutation-based cryptography; bit-slice implementation; routing congestion in wide datapaths.

Graduate · Practice note. Keccak is a block where **wiring, not gate count, determines area**. If post-synthesis area greatly exceeds a gate-count estimate, congestion is usually the reason and RTL changes will not fix it. Include a routing factor in early estimates.

5 // Keccak full round logic based on given input 'Width'
6 // e.g. Width 800 requires 22 rounds
7 //
8 // This module has two phases:
9 // 1. Compute Theta, Rho, Pi steps.
10 // 2. Computes Chi and Iota steps.
11 //
12 // If masking is not enabled, the two phases are completed
within a single
13 // clock cycle.
14 //
15 // If masking is enabled, the first phase (Phase1) completes
in one cycle.
16 // The second phase then needs three clock cycles to complete:
17 // 1. In the first clock cycle, the first stage of Chi is com-
puted for the
18 // first lane halves.

19 // 2. In the second clock cycle, the module writes the updated
first lane
20 // halves to the state.

21 // 3. In the third clock cycle, the new second lane halves are
written to
22 // to the state.
23 //
24 // To deter SCA, we randomly decide which lane halves to pro-
cess first on a
25 // per-round basis. We use additional randomness generated by
the PRNG to take
26 // this decision (rand_aux_i). For more details, refer to the
comments inside
27 // the FSM below.
28 //
29 // If masking is enabled, this implementation uses both ran-
domness provided

```

```

30 // from an external PRNG as well as intermediate results for
remasking the DOM
31 // multipliers below. Per clock cycle, 800b of pseudo-random
data (PRD) are
32 // required. A carefully designed schedule ensures to only
ever update the input
33 // data of the DOM multipliers when also providing fresh ran-
domness and vice
34 // versa. Updating one without the other could lead to un-
desired SCA leakage.

600 // Message FIFO empty interrupt
601 //
602 // The message FIFO empty interrupt is **not useful** for
software if:
603 // - One of the hardware application interfaces is actively
using the KMAC block. In this case
604 // the message FIFO is managed entirely by the application
interface.
605 // - The SHA3 core is not in the Absorb state. Only in this
state, the FIFO is writeable by
606 // software anyway.
607 // - Software has already written the Process command. The
KMAC block will now empty the
608 // message FIFO and load its content into the SHA3 core,
add the padding and then perform

```

```

615 // the final absorption. Software cannot append the mes-
sage further.
616 //
617 // The message FIFO empty interrupt can be **useful** for
software in particular if:
618 // - The message FIFO was completely full previously. How-
ever, unless the KMAC block is currently
619 // processing a block or waiting for fresh entropy from
EDN, it always empties the message FIFO
620 // faster than software can fill it up, meaning the mes-
sage FIFO is empty most of the time.
621 // Note, the empty status is signaled only once after the
FIFO was completely full. The FIFO
622 // needs to be full again for the empty status to be
signaled again next time it's empty.

5 // KMAC Application interface
6 //
7 // This module implements the app interface which arbitrates
8 // between the SW interface and up to
9 // NumAppIntf hardware app interfaces. While a session is act-
10 // ive (either an app or SW), other
11 // requests are stalled.
12 //
13 // There are two kind of app interfaces: Static interfaces
14 // which have a configuration defined at
15 //
16 // compile-time and only a one-shot digest can be retrieved. A
17 // dynamic interface can send the
18 // desired hashing configuration at run time and supports XOF
19 // operation.

OpenTitan CSRNG (SP800-90A)

What this is. A CTR_DRBG deterministic random bit generator with arbitration among multiple requesters.

Why it exists. Because the standard prescribes a procedure, not merely an output. Instantiate, reseed, generate and un-instantiate form a specified state machine with specified counter limits, and certification requires conformance to it.

Undergraduate review · EECS concepts. Pseudorandom versus cryptographically secure generation; forward and backward secrecy; entropy pool management; state machine design.

Graduate · Practice note. Verification here means “does it follow the specified procedure?” The NIST CAVP vectors are effectively the specification. This is a block where inventiveness in the model is a liability rather than an asset.

OpenTitan 엔트로피원 (SP800-90B)

What this is. Extracts entropy from a physical noise source and runs continuous health tests on it.

Why it exists. Because a broken noise source that keeps producing output is worse than one that stops. Physical sources can become stuck or biased, and keys derived from them would be predictable. The standard therefore mandates repetition-count and adaptive-proportion tests running at all times.

Undergraduate review · EECS concepts. Min-entropy as the security-relevant measure; statistical hypothesis testing; ring-oscillator jitter arising from thermal noise.

Graduate · Practice note. This block cannot be validated by simulation. RTL verification covers the test logic; actual entropy quality is measured on silicon. A modelling engineer should state that boundary explicitly in the verification plan rather than let it be assumed away.

2145 // Signal a recoverable alert when dropping tested entropy
bits.
2146 //-----
2147
2148 // Post-health test entropy bits can be dropped from the
pipeline in case of e.g. backpressure
2149 // from the conditioner. The conditioner will still use the
amount of bits configured in
2150 // HEALTH_TEST_WINDOW.FIPS_WINDOW to produce the seed, and
the produced seed is okay to use.
2151 // But as the dropped bits are still tested, the effective
test window increases beyond the
2152 // value configured in HEALTH_TEST_WINDOW.FIPS_WINDOW.
2153 // Signaling this condition serves the following purposes:
2154 // 1. When running in Firmware Override: Observe mode, drop-
ping post-health test entropy bits
2155 // may cause the entropy bits observed from the Observe
FIFO to be non-contiguous, causing
2156 // the observed bits to be not usable for validation pur-
poses. Note that Firmware Override:
2157 // Extract & Insert mode is not affected by this.
2158
2159 // 2. It allows the DV environment to know when entropy bits
have been dropped which simplifies
2160 // DV.
2161 // 3. It helps tuning the depth of the distr FIFO which can
be used to absorb the backpressure
2162 // of the conditioner.

2488 // The amount of entropy consumed to generate a 384-bit seed
depends on the mode of operation:
2489 // - In FIPS/CC compliant mode,
HEALTH_TEST_WINDOWS.FIPS_WINDOW x 4 bits (by default 2048 bits)
2490 // are required to produce one 384-bit seed. For the first
seed after start up, the number of
2491 // bits consumed is doubled to align with the required
1024 samples of 4 bits for startup
2492 // health testing.
2493 // For windows which fail a health test, the entropy is
still absorbed by the SHA3 engine
2494 // but no seed is produced. In order for the SHA3 engine
to produce a seed, the last window it

```

```

2493 // absorbed must have passed the health tests.
2494 // - In Firmware Override: Extract & Insert mode, the operation of
the SHA3 engine is software
2495 // defined.
2496 //
2497 // Note that the final absorption operation of the SHA3 engine is
triggered by the main state
2498 // machine (upon receiving the health-test done pulse). Depending
on the backpressure currently
2499 // experienced in the pipeline, the sha3_process pulse needs to
be delayed to allow all bits in
2500 // the postht, distr and precon FIFOs to be absorbed first. The
SHA3 engine is also triggered
2501 // internally by the padding logic whenever 832 bits (= the rate or
block size of SHA3-384) have
2502 // been received.
2503 //
2504 // Note on backpressure handling from the SHA3 engine:
2505 // To avoid inferring a combo loop, the msg_valid_i input
(pfifo_cond_push signal) must not
2506 // depend on the msg_ready_o output (sha3_msgfifo_ready). However,
we can always push into the
2507 // SHA3 engine as long as the precon FIFO contains valid data. The
ready output is just used to
2508 // determine when to pop from the precon FIFO.
2509 //
2510 // The postht FIFO must be completely empty when the health-test
done pulse is signaled to the
2511 // main state machine. Note that since the postht FIFO is a
packer FIFO, observing the not_empty
2512 // output signal is not sufficient. The only exception is when the
pipeline is entirely full.
2513 // logic [PostHTFifoDepthW-1:0] unused_pfifo_postht_depth;

5 // Description: Logic module indicate ongoing activity of
6 // after disablement of entropy_src_core
7 // The entropy_src has a great deal of internal state, and

```

```

when shutting down most of this internal
8 // state should be cleared. (The two notable exceptions are
the health test statistics, which are
9 // only cleared at the next enable, and the SHA3 conditioning
sponge which accumulates unused
10 // entropy until a seed is generated). There are delays as
incoming RNG data is processed, and for
11 // ease of verification we insist all elements of the data
pipeline are cleared consistently. This
12 // means that once an RNG sample enters the pipeline, that
sample should be reflected in the health
13 // tests. The SHA3 conditioner is also assumed to successfully
absorb every 64-bits that enters the
14 // module.
15 //
16 // To achieve this consistency goal the entropy_src delays the
clearing of internal data buffers
17 // and the state machine until:
18 // 1. Any unprocessed data has been counted at the health
checks (regardless of the mode)
19 // 2. Any RNG data bound for the SHA conditioner has been re-
ceived at the conditioner.
20 // 3. Any ongoing SHA processing operations have completed,
and the main FSM has been forced
21 // back to idle.
22 //
23 // This block creates a modified version of the enable pulse
which:
24 // 1. Postpones the disable event until any flowing data has
passed through the RNG, ESBIT, POSTHT
25 // and DISTR FIFOs. If backpressure is encountered at the
Precon FIFO, the stalled data can
26 // be discarded, and so has a maximum time limit of
MaxFifoWait=4 clocks is given for this
27 // check.
28 // 2. Once the disable signal is received, the rising edge
does not occur until:
29 // 2a. One clock after the falling edge OR
30 // 2b. One clock after the SHA engine completes,
31 // Whichever comes later.

OpenTitan OTBN -- 빅넘버 코프로세서

What this is. A programmable coprocessor for wide-integer arithmetic, with its own instruction set, register file and modular multiplier.

Why it exists. Because public-key cryptography needs modular exponentiation on operands of hundreds or thousands of bits. A general-purpose CPU is too slow; a fixed-function engine cannot follow algorithm changes such as curve replacement or the transition to post-quantum schemes.

Undergraduate review · EECS concepts. Modular arithmetic; Montgomery multiplication (modular reduction without division); constant-time implementation; instruction set design.

Graduate · Practice note. Fixed-function versus programmable is a central IP business decision. **Where the standards move, programmability wins** — which is the situation in cryptography right now.

6 /**
7  * OTBN alu block for the bignum instruction subset
8  *
9  * This ALU supports all of the 'plain' arithmetic and logic
  bignum instructions and some
10  * vectorized arithmetic instructions. BN.MULQACC and its vec-
  torized counterparts are
11  * implemented in a separate block.
12  *
13  * One barrel shifter and two adders (X and Y) are implemented
  along with the logic operators
14  * (AND, OR, XOR, NOT), a vector transposer and 24-bit to 32-bit
  packing and unpacking logic.
15  *
16  * The adders have 256-bit operands with a carry_in and op-
  tional invert on the second operand. This
17  * can be used to implement subtraction (a - b == a + ~b + 1).
  BN.SUBB/BN.ADDC are implemented by
18  * feeding in the carry flag as carry in rather than a fixed 0 or
  1. These 256-bit operands can
19  * also be interpreted as vectors with 32-bit elements.
20  *
21  * The shifter takes a 512-bit input (to implement BN.RSHI,
  concatenate and right shift) and shifts
22  * right by up to 256-bits. The lower (256-bit) half of the
  input and output can be reversed to
23  * allow left shift implementation. There is no concatenate
  and left shift instruction so reversing
24  * isn't required over the full width.
25  *
26  * The dataflow between the adders and shifter is in the dia-
  gram below. This arrangement allows the
27  * implementation of the pseudo-mod (BN.ADDM(V)/BN.SUBM(V))
  instructions in a single cycle whilst
28  * minimising the critical path. The pseudo-mod instructions
  do not have a shifted input so X can
29  * compute the initial add/sub and Y computes the pseudo-mod
  result. The result is selected based
30  * on the carries of adder X and Y. This selection logic is
  implemented in the modulo result
31  * selector. For all other add/sub operations, Y computes the
  operation with one of the inputs
32  * supplied by the shifter and the other from operand_a. The
  result is then pushed through the
33  * modulo result selector. This allows to save one input to
  the final result selection mux.
34  *
35  * The shifter gets supplied with either operand_a and oper-
  and_b or a dense representation thereof
36  * to implement the packing functionality. In addition, the
  shifter gets a shift amount (shift_amt)
37  * and can use 0 instead of operand_a / its dense representa-
  tion. The shifter concatenates both
38  * inputs together before shifting with operand_a in the upper
  (256-bit) half (A/0, B). This
39  * allows the shifter to pass through operand_b simply by not
  performing a shift.
40  *
41  * The shifter result has no direct connection to the final
  result MUX but the result is pushed
42  * through the logic block with operand_a set to 0 and the lo-
  gic operation set to OR. This saves
43  * one input to the result selection mux.
44  *
45  * The vector packing and unpacking is implemented using the
  shifter's concatenation feature and
46  * some wiring.
47  *
48  * Blanking is employed on the ALU data paths. This holds un-
  used data paths to 0 to reduce side
49  * channel leakage. The lower-case 'b' on the diagram below
  indicates points in the data path that
50  * get blanked. Note that Adder X is never used in isolation,
  it is always combined with Adder Y so
51  * there is no need for blanking between Adder X and Adder Y.
52  *
53  * Due to this blanking only one of the possible results can
  be active at the same time. This
54  * allows to implement the final result selection with one

```

```

256-bit OR. This is more area as well
55 * as timing efficient compared to a regular 256-bit mux.

nonzero entry may not be a problem if we
1402 // don't actually use the data.
1403 //
1404 // The situations when the data is actually used are:
1405 //
1406 // (1) This is a bignum instruction that writes back to
the bignum register file by reading an
1407 // ISPR. In this case, we actually pass the data
through with integrity bits, but it
1408 // shouldn't hurt to add fault detection at this
point.
1409 //
1410 // (2) This instruction consumes the data by selecting a
word from an ISPR and then writing it
1411 // back. This happens for things like CSRRS instruc-
tions, where the data flows to the base
1412 // register file through rf_base_wr_data_no_intg_o and
back to the ISPR through
1413 // ispr_base_wdata_o. The word used is given by the
onehot ispr_word_sel_base mask.
1414 //
1415 // In both cases, there's a special case for the
RND_PREFETCH register, which doesn't actually

SPI 호스트

What this is. An SPI master: clock divider, CPOL/CPHA modes, FIFOs, segmented transfers.

Why it exists. Because it is the archetype of a block that looks trivial and has many variants. Four clock modes, bit order, half- and full-duplex, dual and quad IO, and chip-select timing all differ between peripherals.

Undergraduate review · EECS concepts. Serial communication; clock phase and polarity; setup and hold margins; clock division.

Graduate · Practice note. Most SPI field failures trace to CPOL/CPHA combinations or chip-select timing. A verification plan that does not exercise all four modes will leave one broken.

54 // Unlike the configopts fields, the segment fields can
change in back-to-back segment operation.
55 // (If a change in only the configopts fields is detected,
the FSM transitions to idle instead).
56 // For that reason, when using the segment fields in back-
to-back operations, we have to bear
57 // in mind context and determine whether it is appropriate
to use the value for the previous
58 // segment or the following segment.
59 // For instance, the cmd_rd_en signal is sometimes used to
push segment bytes into the shift
60 // register, and so in that case it is important to use
cmd_rd_en_q in that sense. The same
61 // signal is consulted to load the bit counter at the /be-
ginning/ of each byte or dummy cycle,
62 // and so in this context it is appropriate to use
cmd_rd_en_d (which refers to the value from
63 // the immediately following segment).

I2C 컨트롤러

What this is. An I2C controller supporting clock stretching, arbitration and multi-master operation.

Why it exists. Because I2C is an open-drain bidirectional bus, which makes it unusual from a digital design viewpoint: targets may stretch the clock, and simultaneous masters must arbitrate. Neither behaviour fits a simple shift register.

Undergraduate review · EECS concepts. Open-drain / wired-AND signalling; bus arbitration; input filtering and debouncing.

Graduate · Practice note. Clock stretching is frequently unimplemented, and that omission is a recurring field failure. Check for it in any I2C IP you evaluate, and state it explicitly in any you sell.

UART

What this is. An asynchronous serial transceiver with baud generation, oversampled receive, FIFOs and error flags.

Why it exists. Because it is the bring-up lifeline. When a chip does not boot, the UART is often the only visible output, so it must be the simplest and most robust block on the die.

Undergraduate review · EECS concepts. Asynchronous communication; oversampling and majority voting; tolerance to clock frequency error (typically $\pm 2\%$); framing errors.

Graduate · Practice note. Compute and publish the baud-rate error for the intended system clocks. If the ratio is not close to integral, accumulated error drops bits near the end of a frame. A table of achievable baud rates and their errors is a mark of a well-documented UART.

USB 디바이스

What this is. A full-speed USB device controller: endpoints, packet handling, bus state machine.

Why it exists. Because it illustrates a deep protocol stack. Above the differential signalling sit packets, transactions, transfers and enumeration, and deciding which layers are hardware and which are firmware is the principal architectural choice.

Undergraduate review · EECS concepts. Layered protocols; bit stuffing; NRZI encoding; clock recovery from SOF; CRC.

Graduate · Practice note. State the hardware/firmware split in the datasheet. Without it, integrators assume the hardware performs enumeration and discover otherwise late.

80
81 // If the receive path is set NOT to use an external differ-
  ential receiver:

```

```

82 // This block samples data purely from the usb_dp_i/usb_dn_i
pair.
83 // There is a chance that one of the signals in the pair
will appear to have
84 // changed to the new state while the other is still in the
old state. The
85 // following state machine detects transitions and waits an
extra sampling clock
86 // before decoding the state on the dp/dn pair. This trans-
ition period will

87 // only ever last for one clock as long as there is no noise on
the line.

88 // If there is enough noise on the line then the data may be
corrupted and the
89 // packet will fail the data integrity checks.
90
91 // If the receive path uses an external differential receiv-
er:
92 // This block uses the usb_d_i input to detect K and J sym-
bols.
93 // The individual signals of the differential pair must
still be connected
94 // to this block to detect SE0.
95 // Note that the spec warns in section 7.1.4.1:
96 // Both D+ and D- may temporarily be less than VIH (min)
during differential

97 // signal transitions. This period can be up to 14 ns (TFST)
for full-speed
98 // transitions and up to 210 ns (TLST) for low-speed trans-
itions. Logic in the
99 // receiver must ensure that this is not interpreted as an
SE0.
100 // Since the 48MHz sample clock is 20.833ns period we will
either miss this or
101 // sample it only once, so it will be covered by
line_state=DT and the next
102 // sample will not be SE0 unless this was a real SE0 trans-
ition
103 // Note: if it is a real SE0 the usb_d_i input could be do-
ing anything.

RISC-V 타이머

What this is. The mtime/mtimecmp registers and timer interrupt generation.

Why it exists. Because the privileged specification defines its behaviour exactly, leaving almost no implementation freedom. Verification reduces to conformance.

Undergraduate review · EECS concepts. Timers and counters; interrupt controllers; atomicity of wide counter reads.

Graduate · Practice note. Reading a 64-bit counter over a 32-bit bus can tear if the value rolls over between the two halves. Either the read order is specified or a shadow register is required — a classic and easily missed defect.

RISC-V 디버그 모듈

What this is. A RISC-V debug module with JTAG transport and core control.

Why it exists. Because it is the only window into a chip that will not boot. It must therefore operate while the core is halted, which usually places it in a separate clock and reset domain.

Undergraduate review · EECS concepts. JTAG TAP state machine (IEEE 1149.1); boundary scan; debug transport; clock domain crossing.

Graduate · Practice note. Debug access crosses the security boundary. Production devices lock it according to life-cycle state. **The tension between debuggability and security is a design issue in every secure chip**, and the resolution must be specified, not improvised.

137
138   // In order to keep a RV_DM JTAG debug session alive during
NDM reset, we need to memorize the
139   // state of lc_hw_debug_en, since OTP/LC will be reset as
part of NDM reset (the only parts not
140   // reset are in the pwr/rst/clkmgrs, RV_DM and this strap
sampling module). We sample the life
141   // cycle signal state when the strap sampling pulse is as-
serted but the PWRMGR. This pulse is
142   // asserted once during boot (and not after an NDM reset).
143   //
144   // Note that we make sure to invalidate the sampled
lc_hw_debug_en whenever lc_check_byp_en or
145   // lc_escalate_en are not OFF. lc_escalate_en is asserted as
part of an escalation, and
146   // lc_check_byp_en is asserted whenever a life cycle trans-
ition is initiated (it causes the OTP
147   // controller to skip background checks on the life cycle
partition as it undergoes
148   // modification). This makes sure that the sampled value
here does not survive a life cycle
149   // transition.
150   //
151   // Finally, note that there is secondary gating on the RV_DM
and DFT TAPS that is always consuming
152   // live lc_hw_debug_en and lc_dft_en signals for added pro-
tection.

TL-UL 버스 구조

What this is. TileLink Uncached Lightweight adapters, sockets, FIFOs and error responders.

Why it exists. Because a common bus is what makes IP reuse practical. One interface convention permits shared register generators, verification IP and address decoders across every peripheral.

Undergraduate review · EECS concepts. Bus protocols; handshaking; address decoding; arbitration; pipelining and throughput.

Graduate · Practice note. Bus adapters are not free. For a small peripheral the adapter can exceed the function in area. **Resource reports should state whether the adapter is included.**

5 // tlul_adapter (Host adapter) converts basic req/grant/rvalid
into TL-UL interface. If
6 // MAX_REQS == 1 it is purely combinational logic. If MAX_REQS > 1
flops are required.
7 //
8 // The host driving the adapter is responsible for ensuring it
doesn't have more requests in flight
9 // than the specified MAX_REQS.
10 //
11 // The outgoing address is always word aligned. The access
size is always the word size (as

```

```

12 // specified by TL_DW). For write accesses that occupy all
lanes the operation is PutFullData,
13 // otherwise it is PutPartialData, mask is generated from
be_i. For reads all lanes are enabled as
14 // required by TL-UL (every bit in mask set).
15 //

16 // When MAX_REQS > 1 tlul_adapter_host does not do anything to
return responses from the TL-UL
17 // interface which could return them out of order. It is the
host's responsibility to either only

18 // have outstanding requests to an address space it knows will
return responses in order or to not
19 // care about out of order responses (note that if read data
is returned out of order there is no
20 // way to determine this).

7 // Tile-Link UL to register interface adapter
8
9 // This module acts as a device, addressed through the TL-UL
  bus. It receives Get, PutPartialData
10 // and PutFullData messages on the A channel. These are read
  or write requests, which are passed to
11 // the register interface on the same cycle. The response from
  the register interface is sent back
12 // to the host as a message on the D channel on the next
  cycle.
13
14 // A module instance performs several checks on A-channel mes-
  sages and only forwards a request to
15 // the register interface if they all pass. These checks are:
16
17 // - A_OPCODE must be Get, PutPartialData or PutFullData.
18
19 // - A_SIZE must be 0, 1 or 2 (giving a 1-, 2- or 4-byte op-
  eration, respectively).
20
21 // - A_ADDRESS must be naturally aligned for the operation
  byte width signaled in A_SIZE.
22
23 // - A_MASK must only be true for active byte-lanes. The pos-
  ition of the first of these active
24 // lanes is calculated from the address, modulo the width
  of the TL-UL data bus.
25
26 // - If the A_USER.INSTR_TYPE value is Mubi4True, A_OPCODE
  must be Get.
27
28 // - Either the A_USER.INSTR_TYPE value must be a value other

```

```

than MuBi4True or the en_ifetch_i
29 // port must be MuBi4True.
30 //
31 // - If the CmdIntgCheck parameter is true then the command
integrity check must pass.
32 //
33 //
34 // ** Parameters
35 //
36 // CmdIntgCheck: If this parameter is true then there is a
"command integrity check". This uses a
37 // tlul_cmd_intg_chk instance to compare integ-
rity checksums from requests on the A
38 // channel. If the integrity checksums don't
match, the adapter doesn't pass the
39 // request to the register interface through
re_o/we_o and the response on the D
40 // channel will then have its D_ERROR flag set.
41 //
42 // EnableRspIntgGen: OpenTitan sends response integrity with
messages on the TL-UL bus. If this
43 // parameter is true, the module will per-
form calculations to send a correct
44 // integrity value in the response's
A_USER.RSP_INTG field.
45 //
46 // EnableDataIntgGen: This parameter is analogous to EnableR-
spIntgGen but controls whether the
47 // module performs calculations to send a
correct integrity value in the
48 // response's A_USER.DATA_INTG field.
49 //
50 // RegAw: The number of bits used for addresses in the re-
gister interface. Higher bits of the
51 // A_ADDRESS field in an A channel message are ignored.
52 //
53 // RegDw: The number of bits used for data words in the re-
gister interface. This is assumed to match
54 // the data width of the TL-UL bus (see the Matched-
Width_A assertion).
55 //
56 // AccessLatency: This adapter always returns TileLink re-
sponses after one cycle, but this parameter
57 // allows it to handle different timings on the
register interface. If AccessLatency
58 // is zero then the adapter expects a combinat-
orial response on the register
59 // interface and flops the result to break
paths and add a cycle delay. If
60 // AccessLatency is one then the adapter ex-
pects a response on the register interface
61 // in the cycle after the re_o/we_o signal goes
high, but then forwards it
62 // combinatorially to the TileLink interface.
Only values 0 and 1 are allowed for
63 // this parameter.
64 //
65 //
66 // ** Ports
67 //
68 // clk_i/rst_ni: Clock and reset.
69 // tl_i/tl_o: Connections to the TL-UL bus.
70 // en_ifetch_i: This mubi4_t port controls whether to allow
read requests from Get messages whose
71 // A_USER.INSTR_TYPE is MuBi4True (considered to be
processor "fetch" requests).
72 // intg_error_o: This port is high when the adapter has detec-
ted a command integrity error. That can
73 // only happen if the CmdIntgCheck parameter is
set.
74 // re_o/we_o: The read-enable and write-enable ports in the
register interface.
75 // addr_o: The address to read or write through the re-
gister interface.
76 // wdata_o: The value to write through the register in-
terface if we_o is true.
77 // be_o: A byte-enable signal, which is true for each
byte-lane where the TL-UL operation's
78 // mask is true.
79 // busy_i: If this input is high then the A channel in-
terface is stalled (by dropping
80 // A_READY), which means that the adapter will
not accept any new operations.
81 // rdata_i: Read data being returned for a read request
through the register interface.
82 // error_i: An error flag in the register interface. This
signals that an error has been seen,
83 // which can be seen in the D channel response
by D_ERROR being high. The D_DATA
84 // response is also set to '1, squashing any
data that might have been returned
85 // through rdata_i.
86 //
87 // ICEBOX(#15822): Note that due to some modules with special
needs (like the vendored-in RV_DM),
88 // this module has been extended so that it

```

```

supports use cases outside of the
89 // generated reg_top module. This makes this
adapter and its parameterization
90 // options a bit heavy.
91 //
92 // We should in the future come back to this
and refactor / align the module and its
93 // parameterization needs.

7 /**
8  * Tile-Link UL adapter for SRAM-like devices
9  */
10 * - Intentionally omitted BaseAddr in case of multiple memory
11 * maps are used in a SoC,
12 * it means that aliasing can happen if target device size
13 * in TL-UL crossbar is bigger
14 * than SRAM size
15 * - At most one of EnableDataIntgGen / EnableDataIntgPt can
16 * be enabled. However it
17 * possible for both to be disabled.
18 * A module can neither generate an integrity response nor
19 * pass through any pre-existing
20 * integrity. This might be the case for non-security crit-
21 * ical memories where there is
22 * no stored integrity AND another entity upstream is
23 * already generating returning integrity.
24 * There is however no case where EnableDataIntgGen and En-
25 * ableDataIntgPt are both true.
26 */

11 // HReqPass: if 1 then host requests can pass through
on empty fifo,
12 // default 1
13 // HRspPass: if 1 then host responses can pass through
on empty fifo,
14 // default 1
15 // DReqPass: (one per device_count) if 1 then device i
requests can
16 // pass through on empty fifo, default 1
17 // DRspPass: (one per device_count) if 1 then device i
responses can
18 // pass through on empty fifo, default 1
19 // HReqDepth: Depth of host request FIFO, default 2
20 // HRspDepth: Depth of host response FIFO, default 2
21 // DReqDepth: (one per device_count) Depth of device i
request FIFO,
22 // default 2
23 // DRspDepth: (one per device_count) Depth of device i
response FIFO,
24 // default 2
25
26 // ExplicitErrs: This module always returns a request error if
dev_select_i
27 // is greater than N-1. If ExplicitErrs is
set then the width
28 // of the dev_select_i signal will be chosen
to make sure that
29 // this is possible. This only makes a dif-
ference if N is a
30 // power of 2.
31
32 // Requests must stall to one device until all responses from
other devices
33 // have returned. Need to keep a counter of all outstanding
requests and
34 // wait until that counter is zero before switching devices.
35
36 // This module will return a request error if the input value
of 'dev_select_i'
37 // is not within the range 0..N-1. Thus the instantiator of
the socket
38 // can indicate error by any illegal value of dev_select_i.
4'b1111 is
39 // recommended for visibility
