385 ///////////////////////////////////////////////////
386 // SEC_CM: CTRL.SPARSE
387 // We use sparse encodings for various critical signals and
must ensure that:
388 // 1. The synthesis tool doesn't optimize away the sparse
encoding.
389 // 2. The sparsely encoded signal is always valid. More pre-
cisely, an alert or SVA is triggered
390 // 3. The alert signal takes on an invalid value.
391 // 3. The alert signal remains asserted until reset even if
the sparse signal becomes valid again
392 // This is achieved by driving the control FSM into the
terminal error state whenever any
393 // sparsely encoded signal becomes invalid.
394 // If any sparsely encoded signal becomes invalid, the
cipher core further immediately de-asserts
395 // the out_valid_o signal to prevent any data from being re-
leased.

5 // AES cipher core control FSM
6 //
7 // This module contains the AES cipher core control FSM oper-
ating on and producing the negated
8 // values of important control signals. This is achieved by:
9 // - instantiating the regular AES cipher core control FSM op-
erating on and producing the positive
10 // values of these signals, and
11 // - inverting these signals between the regular FSM and the
caliptra_prim_buf synthesis barriers.
12 // Synthesis tools will then push the inverters into the actu-
al FSM.

5 // AES cipher core implementation
6 //
7 // This module contains the AES cipher core including, state
register, full key and decryption key
8 // registers as well as key expand module and control unit.
9 //
10 //
11 // Masking
12 // -----
13 //
14 // If the parameter "Masking" is set to one, first-order mask-
ing is applied to the entire
15 // cipher core including key expand module. For details, see
Rivain et al., "Provably secure
16 // higher-order masking of AES" available at https://
eprint.iacr.org/2010/441.pdf .
17 //
18 //
19 // Details on the data formats
20 // -----
21 //
22 // This implementation uses 4-dimensional SystemVerilog arrays to
represent the AES state:

```

```

23 //
24 // logic [3:0][3:0][7:0] state_q [NumShares];
25 //
26 // The fourth dimension (unpacked) corresponds to the differ-
ent shares. The first element holds the
27 // (masked) data share whereas the other elements hold the
masks (masked implementation only).

28 // The three packed dimensions correspond to the 128-bit state
matrix per share. This
29 // implementation uses the same encoding as the Advanced En-
cryption Standard (AES) FIPS Publication
30 // 197 available at https://www.nist.gov/publications/ad-
vanced-encryption-standard-aes (see Section
31 // 3.4). An input sequence of 16 bytes (128-bit, left most
byte is the first one)
32 //
33 // b0 b1 b2 b3 b4 b5 b6 b7 b8 b9 b10 b11 b12 b13 b14 b15
34 //
35 // is mapped to the state matrix as
36 //
37 // [ b0 b4 b8 b12 ]
38 // [ b1 b5 b9 b13 ]
39 // [ b2 b6 b10 b14 ]
40 // [ b3 b7 b11 b15 ] .
41 //
42 // This is mapped to three packed dimensions of SystemVerilog
array as follows:
43 // - The first dimension corresponds to the rows. Thus,
state_q[0] gives
44 // - The first row of the state matrix [ b0 b4 b8
b12 ], or
45 // - A 32-bit packed SystemVerilog array 32h'{ b12, b8, b4,
b0 }.
46 //
47 // - The second dimension corresponds to the columns. To ac-
cess complete columns, the state matrix
48 // must be transposed first. Thus state_transposed =
aes_pkg::aes_transpose(state_q) and then
49 // state_transposed[1] gives
50 // - The second column of the state matrix [ b4 b5 b6
b7 ], or
51 // - A 32-bit packed SystemVerilog array 32h'{ b7, b6, b5,
b4 }.
52 //
53 // - The third dimension corresponds to the bytes.
54 //
55 // Note that the CSRs are little-endian. The input sequence
above is provided to 32-bit DATA_IN_0 -
56 // DATA_IN_3 registers as
57 //
58 // - DATA_IN_0 32h'{ b3 , b2 , b1 , b0 }
59 // - DATA_IN_1 32h'{ b7 , b6 , b4 , b4 }
60 // - DATA_IN_2 32h'{ b11, b10, b9 , b8 }
61 // - DATA_IN_3 32h'{ b15, b14, b13, b12 } .
62 //
63 // The input state can thus be obtained by transposing the
content of the DATA_IN_0 - DATA_IN_3
64 // registers.
65 //

66 // Similarly, the implementation uses a 3-dimensional array to
represent the AES keys:
67 //
68 // logic [7:0][31:0] key_full_q [NumShares]
69 //

70 // The third dimension (unpacked) corresponds to the different
shares. The first element holds the
71 // (masked) key share whereas the other elements hold the
masks (masked implementation only).

72 // The two packed dimensions correspond to the 256-bit key per
share. This implementation uses
73 // the same encoding as the Advanced Encryption Standard (AES)
FIPS Publication
74 // 197 available at https://www.nist.gov/publications/ad-
vanced-encryption-standard-aes .
75 //
76 // The first packed dimension corresponds to the 8 key words.
The second packed dimension
77 // corresponds to the 32 bits per key word. A key sequence of
32 bytes (256-bit, left most byte is
78 // the first one)
79 //
80 // b0 b1 b2 b3 b4 b5 b6 b7 b8 b9 b10 b11 b12 b13 b14
b15 ... b28 b29 b30 b31
81 //
82 // is mapped to the key words and registers (little-endian) as
83 //
84 // - KEY_SHARE0_0 32h'{ b3 , b2 , b1 , b0 }
85 // - KEY_SHARE0_1 32h'{ b7 , b6 , b4 , b4 }
86 // - KEY_SHARE0_2 32h'{ b11, b10, b9 , b8 }
87 // - KEY_SHARE0_3 32h'{ b15, b14, b13, b12 }
88 // - KEY_SHARE0_4 32h'{ . . . . }
89 // - KEY_SHARE0_5 32h'{ . . . . }
90 // - KEY_SHARE0_6 32h'{ . . . . }
91 // - KEY_SHARE0_7 32h'{ b31, b30, b29, b28 } .
92 //

348         // Extract randomness for masking the input data.
349         //
350         // The masking PRNG is used for generating both the PRD for
the S-Boxes/SubBytes operation as
351         // well as for the input data masks. When using any of the
masked Canright S-Box implementations,
352         // it is important that the SubBytes input masks (generated
by the PRNG in Round X-1) and the
353         // SubBytes output masks (generated by the PRNG in Round X)
are independent. This can be achieved
354         // by using e.g. an unrolled Bivium stream cipher primitive
inside the PRNG. Since the input data
355         // masks become the SubBytes input masks in the first round,
we select the same 8 bit lanes for
356         // the input data masks which are also used to form the Sub-
Bytes output mask for the masked
357         // Canright S-Box implementations, i.e., the 8 LSBs of the
per S-Box PRD. In particular, we have:

```

```

358 //
359 // prd_masking = { prd_key_expand, ... , sb_prd[4],
sb_out_mask[4], sb_prd[0], sb_out_mask[0] }
360 //
361 // Where sb_out_mask[x] contains the SubBytes output mask
for byte x (when using a masked
362 // Canright S-Box implementation) and sb_prd[x] contains ad-
ditional PRD consumed by SubBytes for
363 // byte x.
364 //
365 // When using a masked S-Box implementation other than Can-
right, we still select the 8 LSBs of
366 // the per-S-Box PRD to form the input data mask of the cor-
responding byte. We do this to
367 // distribute the input data masks over all output bits the
masking PRNG. We do the extraction on
368 // a row basis.

PULP 기본 셀 (FIFO·CDC·아비터)

What this is. The PULP platform's common cells: FIFOs, two-phase and Gray-coded CDC, round-robin arbiter trees, stream registers and spill registers.

Why it exists. Because every SoC needs them and getting them wrong is expensive. The spill register in particular exists to break the combinational valid/ready loop that appears whenever two modules are connected directly.

학부 복습 · **EECS concepts.** Metastability; Gray coding; handshake protocols; arbitration; pipeline decoupling.

석사 수준 · **Practice note.** Read `cc_spill_register.sv` closely. It solves a problem — the zero-delay handshake cycle — that is invisible when each module is tested alone and appears immediately on integration.

15 /// Address Decoder: Maps the input address combinatorially to an
  index.
16 /// The address map `addr_map_i` is a packed array of rule_t
  structs.
17 /// The ranges of any two rules may overlap. If so, the rule
  at the higher (more significant)
18 /// position in `addr_map_i` prevails.
19 ///
20 /// There can be an arbitrary number of address rules. There
  can be multiple
21 /// ranges defined for the same index. The start address has
  to be
22 /// less than the end address.
23 ///
24 /// There is the possibility to add a default mapping:
25 /// `en_default_idx_i`: Driving this port to `1'b1` maps all
  input addresses
26 /// for which no rule in `addr_map_i` exists to the default
  index
27 /// specified by
28 /// `default_idx_i`. In this case, `dec_error_o` is always
  `1'b0`.
29 ///
30 ///
31 /// The `Napot` parameter allows using naturally-aligned power of
  two (NAPOT) regions,
32 /// using base addresses and masks instead of address ranges
  to specify rules.
33 ///
34 ///
35 /// Assertions: The module checks every time there is a change in
  the address mapping
36 /// if the resulting map is valid. It fatals if `start_addr`
  is higher than `end_addr` (non-NAPOT

```

```

33 /// only) or if a mapping targets an index that is outside the
  number of allowed indices.
34 /// It issues warnings if the address regions of any two map-
  pings overlap (non-NAPOT only).
35 module cc_addr_decode #(

16 /// `cc_cb_filter`: This module implements a counting bloom
17 // filter with parameterizable hash functions.
18 //
19 // Functionality: A counting bloom filter is a data structure
20 // to efficiently implement
21 // set lookups. It does so by hashing its data
22 // inputs onto multiple pointers
23 // which serve as indicators for an array of
24 // buckets. For lookups can be
25 // false positives, but no false negatives.
26 // - Seeding: The pseudo random generators need seeds at
27 // elaboration time to generate
28 // different hashes. In principle any combina-
29 // tion of seeds can be used.
30 // But one should look that the hash outputs
31 // give sufficient different patterns,
32 // such that the resulting collision rate is
33 // low. The package `cc`
34
35 // contains the struct for seeding the PRG's in
36 // the hash functions.
37 // - Lookup:
38 // - Ports: `look_data_i`, `look_valid_o`
39 // - Description: Lookup combinational, `look_valid_o` is
40 // high, when `look_data_i` was
41 // previously put into the filter.
42 // - Increment:
43 // - Ports: `incr_data_i`, `incr_valid_i`
44 // - Description: Put data into the counting bloom filter,
45 // when valid is high.
46 // - Decrement:
47 // - Ports: `decr_data_i`, `decr_valid_i`
48 // - Description: Remove data from the counting bloom fil-
49 // ter. Only remove data that was
50 // previously put in, otherwise will go in a
51 // wrong state.
52 // - Status:
53 // - `clr_i`: Clears the filter and sets all coun-
54 // ters to 0.
55
56 // - `filter_usage_o`: How many data items are currently in
57 // the filter.
58 // - `filter_full_o`: Filter is full, can no longer hold
59 // more items.
60 // - `filter_empty_o`: Filter is empty.
61 // - `filter_error_o`: One of the internal counters or
62 // buckets overflowed.

14 /// A two-phase clock domain crossing.
15 ///
16 /// # Reset Behavior!!
17 ///
18 /// This module must not be used if warm reset capability is a
requirement. The
19 /// only exception is if you consistently use a reset controller
that sequences
20 /// the resets while gating both clock domains (be very careful
if you follow
21 /// this strategy!). If you need warm reset/clear/flush capabilities,
use (AND
22 /// CAREFULLY READ THE DESCRIPTION) the
cc_cdc_2phase_clearable module.
23 ///
24 /// After this disclaimer, here is how you connect the
src_rst_ni and the
25 /// dst_rst_ni of this module for power-on-reset (POR). The
src_rst_ni and
26 /// dst_rst_ni signal must be asserted SIMULTANEOUSLY (i.e.
asynchronous
27 /// assertion). Otherwise, spurious transactions could occur
in the domain
28 /// where the reset arrives later than the other. The de-assertion
of both reset
29 /// must be synchronized to their respective clock domain
(i.e. src_rst_ni must
30 /// be deasserted synchronously to the src_clk_i and
dst_rst_ni must be
31 /// deasserted synchronously to dst_clk_i.) You can use the
cc_rstgen cell in the
32 /// common_cells library to achieve this (synchronization of
only the
33 /// de-assertion). However, be careful about reset domain
crossings; If you
34 /// reset both domain asynchronously in their entirety (i.e.
POR) you are fine.
35 /// However, if you use this strategy for warm resets (some
parts of the circuit
36 /// are not reset) you might introduce metastability in this
separate
37 /// reset-domain when you assert the reset (the deassertion
synchronizer doesn't
38 /// help here).

17 // Description: Clearable Two-Phase CDC
18 // Transfer payloads with a two-phase handshake while coordin-
ating synchronous
19 // and optional asynchronous one-sided clears across source
and destination.
20
21 /// A two-phase clock domain crossing.
22 ///
23 /// CONSTRAINT: Requires max_delay of min_period(src_clk_i,
dst_clk_i) through
24 /// all asynchronous paths between the domains. The payload
CDC uses
25 /// async_payload_req, async_payload_ack, and
async_payload_data for the actual
26 /// data handshake. The clear sequencer CDCs use
async_reset_src2dst_req,
27 /// async_reset_dst2src_ack, async_reset_src2dst_next_phase,
28 /// async_reset_dst2src_req, async_reset_src2dst_ack, and
29 /// async_reset_dst2src_next_phase to handshake the clearing
state machines.
30 ///
31 ///
32 /// Reset Behavior:
33 ///
34 /// In contrast to the cc_cdc_2phase version without clear
signal, this module
35 /// supports one-sided warm resets (asynchronously and syn-
chronously). The way
36 /// this is implemented is described in more detail in the
cc_cdc_reset_ctrlr
37 /// module. To summarize a synchronous clear request i.e. src/

```

```

dst_clear_i will
38 /// cause the respective other clock domain to reset as well
without introducing
39 /// any spurious transactions. This is accomplished by an in-
ternal module
40 /// (cc_cdc_reset_ctrlr) that starts a reset sequence on both
sides of the CDC in
41 /// lock-step that first isolates the CDC from the outside
world and then resets
42 /// it. The reset sequencer provides the following behavior:
43 /// 1. There are no spurious invalid or duplicated transac-
tions regardless how
44 /// the individual sides are reset (can also happen roughly
simultaneously)
45 /// 2. The CDC becomes unready at the src side in the next
cycle after
46 /// synchronous reset request until the reset sequence is
completed. A currently
47 /// pending transactions might still complete (if the dst
accepts at the
48 /// exact time the reset is request on the src die).
49 /// 3. During the reset sequence the dst might withdraw the
valid signal. This
50 /// might violate higher level protocols. If you need this
feature you would
51 /// have to patch the existing implementation to wait with
the isolate_ack
52 /// assertion until all open handshakes were acknowledged.
53 /// 4. If the parameter ClearOnAsyncReset is enabled, the same
behavior as
54 /// above is also valid for asynchronous resets on either
side. However, this
55 /// increases the minimum number of synchronization stages
(SyncStages
56 /// parameter) from 2 to 3 (read the cc_cdc_reset_ctrlr
header to figure out
57 /// why).
58 ///
59 ///

21 //
22 // A 4-phase clock domain crossing. While this is less effi-
23 // cient than a 2-phase
24 // CDC, it doesn't suffer from the same issues during one
25 // sided resets since
26 // the IDLE state doesn't alternate with every transaction.
27 //
28 // Parameters: data_t - The type of the data to transmit
29 // through the CDC.
30 //
31 // Decoupled - If decoupled is disabled, the 4phase cdc will
32 // not consume the
33 // src item until the handshake with the other side is com-
34 // pleted. This
35 // increases the latency of the first transaction but has no
36 // effect on
37 // throughput. However, critical paths might be slightly
38 // longer. Use this mode
39 // if you want to ensure that there are no in-flight transac-
40 // tions within the
41 // CDC.

```

```

26 //
27 // SendResetMsg - If send reset msg is enabled, the 4phase
28 // cdc starts sending
29 // the ResetMsg within its' asynchronous reset state. This
30 // can be usefull if
31 // we need to transmit a message to the other side of the CDC
32 // immediately
33 // during an async reset even if there is no clock available.
34 // This mode is
35 // required for proper functionality of the cc_cdc_re-
36 // set_ctrlr module.
37 //
38 // SyncStages - Number of synchronization stages for
39 // async_req and async_ack.
40 //
41 // CONSTRAINT: Requires max_delay of min_period(src_clk_i,
42 // dst_clk_i) through
43 // the paths async_req, async_ack, async_data.
44 //

17 /// A clock domain crossing FIFO, using 2-phase hand shakes.
18 ///
19 /// This FIFO has its push and pop ports in two separate clock
domains. Its size
20 /// can only be powers of two, which is why its depth is given as
2**LogDepth.
21 /// LogDepth must be at least 1.
22 ///
23 /// # Reset Behavior!!
24 ///
25 /// This module must not be used if warm reset capabilty is a
requirement. The
26 /// only exception is if you consistently use a reset control-
ler that sequences
27 /// the resets while gating both clock domains (be very care-
ful if you follow
28 /// this strategy!).
29 ///
30 /// After this disclaimer, here is how you connect the
src_rst_ni and the
31 /// dst_rst_ni of this module for power-on-reset (POR). The
src_rst_ni and
32 /// dst_rst_ni signal must be asserted SIMULTANEOUSLY (i.e.
asynchronous
33 /// assertion). Otherwise, spurious transactions could occur
in the domain
34 /// where the reset arrives later than the other. The de-as-

```

```

section of both reset
35 /// must be synchronized to their respective clock domain
(i.e. src_rst_ni must
36 /// be deasserted synchronously to the src_clk_i and
dst_rst_ni must be
37 /// deasserted synchronously to dst_clk_i.) You can use the
cc_rstgen cell in the
38 /// common_cells library to achieve this (synchronization of
only the
39 /// de-assertion). However, be careful about reset domain
crossings; If you
40 /// reset both domain asynchronously in their entirety (i.e.
POR) you are fine.
41 /// However, if you use this strategy for warm resets (some
parts of the circuit
42 /// are not reset) you might introduce metastability in this
separate
43 /// reset-domain when you assert the reset (the deassertion
synchronizer doesn't
44 /// help here).

16 /// A clock domain crossing FIFO, using gray counters.
17 ///
18 /// # Architecture
19 ///
20 /// The design is split into two parts, each one being clocked
  and reset
21 /// separately.
22 /// 1. The data to be transferred over the clock domain
  boundary is
23 /// is stored in a FIFO. The corresponding write pointer is
  managed
24 /// (incremented) in the source clock domain.
25 /// 2. The entire FIFO content is exposed over the
  `async_data` port.
26 /// The destination clock domain increments its read pointer
  er
27 /// in its destination clock domain.
28 ///
29 /// Read and write pointers are then gray coded, communicated
30 /// and synchronized using a classic multi-stage FF synchronizer
31 /// in the other clock domain. The gray coding ensures that
  only
32 /// one bit changes at each pointer increment, preventing the
33 /// synchronizer to accidentally latch an inconsistent state
34 /// on a multi-bit bus.
35 ///
36 /// The not full signal e.g. `src_ready_o` (on the sending
  side)
37 /// is generated using the local write pointer and the pessimistic
38 /// read pointer from the destination clock domain (pessimistic
39 /// because it is delayed at least two cycles because of the
  synchronizer
40 /// stages). This prevents the FIFO from overflowing.
41 ///
42 /// The not empty signal e.g. `dst_valid_o` is generated using
43 /// the pessimistic write pointer and the local read pointer
  in
44 /// the destination clock domain. This means the FIFO content
45 /// does not need to be synchronized as we are sure we are
  reading
46 /// data which has been written at least two cycles earlier.
47 /// Furthermore, the read select logic into the FIFO is completely
48 /// clocked by the destination clock domain which avoids
49 /// inefficient data synchronization.
50 ///
51 /// The FIFO size must be powers of two, which is why its
  depth is
52 /// given as 2**LogDepth. LogDepth must be at least 1.
53 ///
54 /// # Reset Behavior!!
55 ///
56 /// This module must not be used if warm reset capability is a
  requirement. The
57 /// only exception is if you consistently use a reset controller
  that sequences
58 /// the resets while gating both clock domains (be very careful
  if you follow

17 /// A clock domain crossing FIFO, using gray counters.
18 ///
19 /// # Architecture
20 ///
21 /// The design is split into two parts, each one being clocked
and reset
22 /// separately.
23 /// 1. The data to be transferred over the clock domain
boundary is
24 /// is stored in a FIFO. The corresponding write pointer is
managed
25 /// (incremented) in the source clock domain.
26 /// 2. The entire FIFO content is exposed over the
`async_data` port.
27 /// The destination clock domain increments its read point-
er
28 /// in its destination clock domain.
29 ///
30 /// Read and write pointers are then gray coded, communicated
31 /// and synchronized using a classic multi-stage FF synchron-
izer
32 /// in the other clock domain. The gray coding ensures that
only
33 /// one bit changes at each pointer increment, preventing the
34 /// synchronizer to accidentally latch an inconsistent state
35 /// on a multi-bit bus.
36 ///
37 /// The not full signal e.g. `src_ready_o` (on the sending
side)
38 /// is generated using the local write pointer and the pessim-
istic
39 /// read pointer from the destination clock domain (pessimist-
ic
40 /// because it is delayed at least two cycles because of the
synchronizer
41 /// stages). This prevents the FIFO from overflowing.
42 ///
43 /// The not empty signal e.g. `dst_valid_o` is generated using
44 /// the pessimistic write pointer and the local read pointer

```

```

in
45 /// the destination clock domain. This means the FIFO content
46 /// does not need to be synchronized as we are sure we are
reading
47 /// data which has been written at least two cycles earlier.
48 /// Furthermore, the read select logic into the FIFO is com-
pletely
49 /// clocked by the destination clock domain which avoids
50 /// inefficient data synchronization.
51 ///
52 /// The FIFO size must be powers of two, which is why its
depth is
53 /// given as 2**LogDepth. LogDepth must be at least 1.
54
55 /// Reset Behavior:
56 ///
57 /// In contrast to the cc_cdc_fifo_gray version without clear
signal, this module
58 /// supports one-sided warm resets (asynchronously and syn-
chronously). The way
59 /// this is implemented is described in more detail in the
cc_cdc_reset_ctrlr
60 /// module. To summarize a synchronous clear request i.e. src/
dst_clear_i will
61 /// cause the respective other clock domain to reset as well
without introducing
62 /// any spurious transactions. This is accomplished by an in-
ternal module
63 /// (cc_cdc_reset_ctrlr) the starts a reset sequence on both
sides of the CDC in
64 /// lock-step that first isolates the CDC from the outside
world and then resets
65 /// it. The reset sequencer provides the following behavior:
66 /// 1. There are no spurious invalid or duplicated transac-
tions regardless how
67 /// the individual sides are reset (can also happen roughly
simultaneously)
68 /// 2. The FIFO becomes unready at the src side in the next
cycle after
69 /// synchronous reset request until the reset sequence is
completed. Some of
70 /// the pending transactions might still complete (if the
dst accepts at the
71 /// exact time the reset is request on the src die), some
of them will be
72 /// dropped (of course still guaranteeing FIFO order).
73 /// 3. During the reset sequence the dst might withdraw the
valid signal. This
74 /// might violate higher level protocols. If you need this
feature you would
75 /// have to patch the existing implementation to wait with
the isolate_ack
76 /// assertion until all open handshakes were acknowledged.
77 /// 4. If the parameter ClearOnAsyncReset is enabled, the same
behavior as
78 /// above is also valid for asynchronous resets on either
side. However, this
79 /// increases the minimum number of synchronization stages
(SyncStages
80 /// parameter) from 2 to 3 (read the cc_cdc_reset_ctrlr
header to figure out
81 /// why).
82 ///
83 ///
84 /// # Constraints
85 ///
86 /// We need to make sure that the propagation delay of the
data, read and write
87 /// pointer is bound to the minimum of either the sending or
receiving clock
88 /// period to prevent an inconsistent state to be latched (if
for example the
89 /// one bit of the read/write pointer have an excessive
delay). Furthermore, we
90 /// should deactivate setup and hold checks on the asynchron-
ous signals.
91 ///
92 /// async_data, async_wptr, and async_rptr are the FIFO stor-
age and pointer CDCs
93 /// for the actual data path. async_reset_src2dst_req,
94 /// async_reset_dst2src_ack, async_reset_src2dst_next_phase,
95 /// async_reset_dst2src_req, async_reset_src2dst_ack, and
96 /// async_reset_dst2src_next_phase are the CDCs for the clear-
ing state machines.

16 // Description: CDC Clear Signaling Synchronization
17 // Coordinate clear and isolate sequencing between two CDC
clock domains so
18 // one-sided reset or clear requests do not break the protec-
ted CDC protocol.
19 //
20 // Detailed Description:
21 // This module is mainly used internally to synchronize the
clear requests
22 // between both sides of a CDC module. It aims to solve the
problem of
23 // initiating a CDC clear, reset one-sidedly without running
into
24 // reset-domain-crossing issues and breaking CDC protocol as-
sumption.
25 //
26 // Problem Formulation:
27 //

28 // CDC implementations usually face the issue that one side of
the CDC must not
29 // be cleared without clearing the other side. E.g. clearing
the write-pointer
30 // without clearing the read-pointer in a gray-counting CDC
FIFO results in an
31 // invalid fill-state an may cause spurious transactions of
invalid data to be
32 // propagated accross the CDC. A similar effect is caused in
2-phase CDC
33 // implementations.
34 //

35 // A naive mitigation technique would be to reset both domains
asynchronously
36 // with the same reset signal. This will cause intra-clock do-
main RDC issues
37 // since the asynchronous clear event (assertion of the reset
signal) might
38 // happen close to the active edge of the CDC's periphery and
thus might induce

39 // metastability. A better, but still flawed approach would be to
naively
40 // synchronize assertion AND deassertion (the usual rst sync
only synchronize
41 // deassertion) of the resets into the respective other do-
main. However, this
42 // might cause the classic issue of fast-to-slow clock domain
crossing where the
43 // clear signal is not asserted long enough to be captured by
the receiving
44 // side. The common mitigation strategy is to use a feedback
acknowledge signal
45 // to handshake the reset request into the other domain. One
even more peculiar
46 // corner case this approach might suffer is the scenario
where the synchronized

47 // clear signal arrives at the other side of the CDC within or
even worse after

48 // the same clock cylice that the other domain crossing signals
(e.g. read/write
49 // pointers) are cleared. In this scenario, multiple signals
change within the
50 // same clock cycle and due to metastability we cannot be
sure, that the other
51 // side of the CDC sees the reset assertion before the first
bits of e.g. the
52 // write/read pointer start to switch to their reset state.
Care must also be

53 // taken to handle the corner cases where both sides are reset
simultaneously or
54 // the case where one side leaves reset earlier than the oth-
er.
55 //
56 // How this Module Works
57 //
58 // This module has two interfaces, the 'a' side and the 'b'
side. Each side can
59 // be triggered using the a/b_clear_i signal or (optionally)
by the asynchronous
60 // a/b_rst_ni. Once e.g. 'a' is triggered it will initiate a
clear sequence that
61 // first asserts an 'a_isolate_o' signal, waits until the ex-
ternal circuitry
62 // acknowledges isolation using the 'a_isolate_ack_i'. Then
the module asserts
63 // the 'a_clear_o' signals before some cycles later, the isol-
ate signal is
64 // deasserted. This sequence ensures that no transactions can
arrive to the CDC

65 // while the state is cleared. Now the important part is, that
those four phases
66 // (asser isolate, assert clear, deassert clear, deassert
isolate) are mirrored
67 // on the other side ('b') in lock-step. The cc_cdc_re-

```

```

set_ctrlr module uses a
68 // dedicated 4-phase handshaking CDC to transmit the current
phase of the clear
69 // sequence to the other domain. We use a 4-phase rather than
a 2-phase CDC to
70 // avoid the issues of one-sided async reset that might trig-
ger spurious
71 // transactions. Furthermore, the 4-phase CDC within this mod-
ule is operated in
72 // a special mode: Decoupled=0 ensures that there are no in-
flight transactions.
73 // The src side only consumes the item once the destination
side acknowledged
74 // the reception. This property is required to transition
through the phases in

75 // lock-step. Furthermore, (SendResetMsg=1) will cause the src
side of the
76 // 4-phase CDC to immediately initiate the isolation phase in
the dst domain

77 // upon asynchronous reset regardless how long the async reset
stays asserted or
78 // whether the source clock is gated. Both sides of this mod-
ule independently

79 // generate the sequence signals as an initiator (triggered by
the clear_i or
80 // rst_ni signal) or receiver (triggered for the other side).
The or-ed version
81 // of initiator and receiver are used to generate the actual
a/b_isolate_o and

82 // a/b_clear_o signal. That way, it doesn't matter wheter both
sides
83 // simultanously trigger a clear sequence, proper sequencing
is still
84 // guaranteed.
85 //
86 // The time it takes to complete an entire clear sequence can
be bounded as follows:
87 //
88 //  $t_{clear} \leq 20 \cdot T + 16 \cdot SyncStages \cdot T$ , with  $T = \max(T_a, T_b)$ 
(clock periods of src and dst)
89 //
90 // How to Use the Module
91 //
92 // Instantiate the module within your CDC and connect a/
b_clk_i, the
93 // asynchronous a/b_rst_ni and the synchronous a/b_clear_i
signals. The 'a' and

94 // 'b' port are entirely symetric so it doesn't matter whether
you connect src
95 // to 'a' or 'b'. If you enable support for async reset
96 // (ClearOnAsyncReset==1), parametrize the number of synchron-
ization stages

97 // (for metastability resolution) to be strictly less than the
latency of the
98 // CDC. E.g. if your CDC uses 3 (the minimum) sync stages,
parametrize this
99 // module with SyncStages < 2! Your CDC must implement a src/
dst_clear_i port
100 // that SYNCHRONOUSLY clears all FFs on the respective side.
Connect the CDC's

101 // src/dst_clear ports to this module's a/b_clear_o port. Once
the a/b_isolate_o
102 // signal is asserted, the respective CDC side (src/dst) must
be isolated from
103 // the outside world (i.e. must no longer accept any transac-
tion on the src side
104 // and cease presenting or even withdrawing data on the dst
side). Once your CDC
105 // side is isolated (depending on protocol this might take
several cycles),
106 // assert the a/b_isolate_ack_i signal.
107 //
108 // include "common_cells/registers.svh"
109 //

215
216 // How this module works:
217
218 // The module is split into two parts. The initiator part
219 consists of an FSM
220 // that is triggered by the clear_i signal and transitions
221 // through reset
222 // sequence. During those transitions, the `initiat-
223 // or_isolate_out` and
224 // `initiator_clear_out` signals are asserted appropriately.
225
226 // The receiver part receives the state transitions from the
227 // other clock
228 // domain (initiator part of the `cc_cdc_reset_ctrlr_half`

```

```

instance in the other
226 // clock domain) and asserts the `receiver_isolate_out` and
227 // `receiver_clear_out` appropriately (considering the
228 // `isolate_ack_i`
229 // signal).
230 // In both, the initiator and the receiver part, the re-
231 // spective FSM
232 // transitions through 4 phases. In the ISOLATE phase, the
233 // isolate signal is
234 // asserted and the connected CDCs are expected to block all
235 // further
236 // interactions with the outside world and acknowledge the
237 // isolation with the
238 // isolate_ack_i signal. In the CLEAR phase, the clear sig-
239 // nal is asserted
240 // which resets the internal state of the CDC while keeping
241 // the isolate signal
242 // asserted. In the POST_CLEAR phase, the clear signal is
243 // deasserted. Finally,
244 // when returning to the IDLE phase, the isolate signal is
245 // deasserted to
246 // continue normal operation. The FSM uses a dedicated 4-
247 // phase handshaking CDC
248 // to transition between the phases in lock-step and trans-
249 // mits the current
250 // state to the other domain to avoid issues if the other
251 // domain is reset

2 // Title : Configurable Integer Clock Divider
3 //
4 // File : cc_clk_int_div.v Author : Manuel Eggimann <meggim-
mann@iis.ee.ethz.ch>
5 // Created : 17.03.2022
6 //
7 // Description :
8 //
9 // This module implements an at runtime configurable integer
10 clock divider that
11 // always generates clean 50% duty cycle output clock. Clock
12 divider setting
13 // changes are handshaked and during the transitioning phase
14 between cc_clk_div
15 // value changes, the output clock is gated to prevent clock
16 glitches and no
17 // other cc_clk_div change request is accepted. clk_o remains
18 gated for at most
19 // 3x<new clk period> clk_i cycles. If the new div_i value
20 equals the currently
21 // configured value, the clock is not gated and the handshake
22 is immediately
23 // granted. It is thus safe to statically tie the valid signal to
24 logic high if
25 // we can guarantee, that the div_i value remains stable long
26 enough (upper
27 // limit 2 output clock cycles).
28 //
29 // The `en_i` signal can be used to enable or disable the out-
30 put clock in a safe
31 // manner.
32 //
33 // If a div value of 0 or 1 is requested, the input clock is
34 feed through to the
35 // output clock. However, the same gating rules apply (again
36 to prevent
37 // glitches).
38 //
39 // If test_mode_en_i is asserted, the output clock gate is by-
40 passed entirely and
41 // clk_o will always be directly driven by clk_i. Use this

```

```

mode for DFT of the
29 // downstream logic.
30 //
31 // Parameters:
32 //
33 // DivValueWidth: The number of bits to use for the internal
34 // counter. Defines the maximum division factor.
35 //
36 // DefaultDivValue: The default division factor to use after
37 reset. Use this
38 // parameter and tie div_valid_i to zero if you don't need at
39 runtime
40 // configurability. An elaboration time error will be issued
41 if the supplied
42 // default div value is not representable with DivValueWidth
43 bits.
44 //
45 // EnableClockInReset: If 1'b1, the clock gate will be enabled
46 during reset
47 // which allows the cc_clk_int_div instance to bypass the
48 clock during reset, IFF
49 // the DefaultDivValue is 1. For all other DefaultDivValues,
50 the output
51 // clock will not be available until rst_ni is deasserted!
52 //
53 // IMPORTANT!!!
54 //
55 // All clock gating/logic within this design is performed by
56 dedicated clock logic
57 // tech cells. By default the common_cell library uses the be-
58 havioral models in
59 // the `tech_cells_generic` repository. However, for synthesis
60 these cells need to be
61 // mapped to dedicated cells from your standard cell library,
62 preferably ones
63 // that are designed for clock logic (they have balanced rise
64 and fall time).
65 // During synthesis you furthermore have to properly set
66 `dont_touch` or
67 // `size_only` attributes to prevent the logic synthesizer
68 from replacing those
69 // cells with regular logic gates which could end up being
70 glitchy!
71 //

1 //-----
2 // Title : Static Integer Clock Divider
3 //-----
4 // File : cc_clk_int_div_static.sv
5 // Author : Manuel Eggimann <meggimann@iis.ee.ethz.ch>
6 // Created : 08.05.2023
7 //-----
8 // Description :
9 //
10 // This module implements a static arbitrary integer divider.
11 // Static in this
12 // case means, the divider value is constant at elaboration
13 // time (SV parameter).
14 // It supports arbitrary integer division with a guaranteed
15 // 50% duty cycle for
16 // odd and even division.
17 //
18 // Internally, this module is wrapper around the "at-runtime"
19 // configurable

```

```

16 // `cc_clk_int_div` module. If you need to change the division
factor at-runtime you

17 // should directly use `cc_clk_int_div` instead. However if all
you need is a single
18 // division factor this module provides a convenience wrapper
for you with a
19 // simplified interface.
20 //
21 // The `en_i` signal can be used to enable or disable the out-
put clock in a safe
22 // manner (there is an internal, glitch-free clock gate).
23 //
24 // Parameters:
25 //
26 // DivValue: The integer value by which the clock shall be di-
vided. Must be
27 // non-zero integer smaller than 2^32-1.
28 //

29 // EnableClockInReset: If 1'b1, the clock gate will be enabled
during reset
30 // which allows the cc_clk_int_div instance to bypass the
clock during reset, IFF
31 // the DefaultDivValue is 1. For all other DefaultDivValues,
the output
32 // clock will not be available until rst_ni is deasserted!
33 //
34 // IMPORTANT!!!
35 //
36 // All clock gating/logic within this design is performed by
dedicated clock
37 // logic tech cells. By default the common_cell library uses
the behavioral

38 // models in the `tech_cells_generic` repository. However, for
synthesis these
39 // cells need to be mapped to dedicated cells from your stand-
ard cell library,
40 // preferably ones that are designed for clock logic (they
have balanced rise
41 // and fall time). During synthesis you furthermore have to
properly set

42 // `dont_touch` or `size_only` attributes to prevent the logic
synthesizer from
43 // replacing those cells with regular logic gates which could
end up being
44 // glitchy!
45 //

1 //-----
2 // Title           : Glitch-free Clock Multiplexer
3 //-----
4 // File            : cc_clk_mux_glitch_free.sv
5 // Author           : Manuel Eggimann <meggimann@iis.ee.ethz.ch>
6 // Created          : 10.12.2022
7 //-----
8 // Description :
9 //
10 // This module allows glitch free clock multiplexing between N
arbitrary input
11 // clock with completely unknown phase relation ships. The
module will make
12 // sure to first synchronize the clock multiplexer signal to
the relevant clock
13 // domains and ensures glitch free switching between the
source clock and the
14 // new target clock by silencing the output at appropriate
times. The clock
15 // signals themselves only pass through: 1 clock-gate, 1 N-in-
put clock-OR Gate,
16 // 1 2-input clock mux. All these cells are referenced from
the tech_cells
17 // repository and thus no conventional logic gate is directly
in the clock path.
18
19 // The correctness of this module is based on the following
assumptions:
20 // 1. The select signal stays stable for a duration of at
least min(clks_i
21 // period)
22 // 2. Glitches on the select signal are shorter than
min(clks_i) - t_setup
23
24 // 3. During a transition from clock input a to clock input b,
both clocks have
25 // a stable period.
26
27 // A clock switching procedure from clock a to clock b has the
following timing behavior:
28 // 1. After at most NumSyncStages clock cycle of clock a, the
output clock is
29 // disabled with its next falling edge.
30 // 2. After clock cycle of clock a and another NumSyncStages
clock cycles of clock b, the output is
31 // enabled with the next rising edge of clock B.
32 // So in total, an upper bound for the worst case clock
switching delay is 2x
33 // NumSyncStages x max(clock_periods)
34 //
35 // The design has a parameter (ClockDuringReset) that allows
the clock
36 // multiplexer to propagate the selected clock even during re-
set assertion.
37 // However, during reset assertion the glitch filtering and
the synchronization
38 // registers are bypassed (since they are frozen in reset
state). Thus no glitch
39 // filtering is performed during reset. This is ok if the
async_sel_i signal
40 // stays constant during reset assertion. Once you deassert
the reset, regular
41 // glitch filtering and synchronization will kick in. However,
you must wait for
42 // at least 1x max(input clock periods) before changing the
async_sel_i after a
43 // reset to be sure the switch to regular operation has com-
pleted. During the
44 // transition from async_reset operation to regular operation
there will be a
45 // short phase where the clock is gated (similar to what hap-
pens when you switch
46 // from one clock to the other).
47 //
48 // IMPORTANT!!!
49 //
50 // All clock gating/logic within this design is performed by

the clock

96 // propagation through an N-input clock OR gate. The crucial
and most critical
97 // part is to make sure that these clock enable signal
transitions are
98 // non-overlapping and have enough timing separation to pre-
vent any glitches

99 // on the clock output during the transition. We ensure this as
follows:
100 //
101 // 1. Decode the sel_i input to a onehot signal.
102 // 2. For each clock input, take the correspondi onehot sig-
nal. For each clock
103 // input we also have a correspondding output clock enable
signal that
104 // controls the corresponding clock's clk gate. We thus and-
gate the one-hot
105 // signal of the current clock with the inverse of every
other clocks enable
106 // signal. In other words, we only allow the propagation of
the onehot enable
107 // signal if the clock is currently disabled.
108 // 3. Filter any glitches on this and-gated signal by
passing it through a
109 // flip-flop clocked by the current clock and and-gating
both the output and
110 // the input. I.e. the output is only becomes active if the
signal stays
111 // stable HIGH for at least one clock period.

```

```

112 // 4. Synchronize this glitch-filtered signal into the cur-
rent clock domain
113 // with an M-stage synchronizer.

AXI4 상호연결

What this is. AXI4 crossbars, multiplexers, demultiplexers, cuts and error slaves.

Why it exists. Because AXI is the de facto SoC interconnect, and because its ordering rules — ordering guaranteed only within an ID — shape every verification component that touches it.

학부 복습 · EECS concepts. Channel-based protocols; out-of-order completion; transaction identifiers; deadlock avoidance in interconnect.

석사 수준 · Practice note. A scoreboard for AXI needs **one queue per ID**. A single queue both reports false failures on legal reordering and accepts genuine intra-ID violations.

15 /// Filter atomic operations (ATOPs) in a protocol-compliant
  manner.
16 ///
17 /// This module filters atomic operations (ATOPs), i.e., write
  transactions that have a non-zero
18 /// `aw_atop` value, from its `slv` to its `mst` port. This
  module guarantees that:
19 ///
20 /// 1) `aw_atop` is always zero on the `mst` port;
21 ///
22 /// 2) write transactions with non-zero `aw_atop` on the `slv`
  port are handled in conformance with
23 /// the AXI standard by replying to such write transactions
  with the proper B and R responses.
24 /// The response code on atomic operations that reach this
  module is always SLVERR
25 /// (implementation-specific, not defined in the AXI stand-

```

```

ard).
26 ///
27 /// ## Intended usage
28 /// This module is intended to be placed between masters that
may issue ATOPs and slaves that do not
29 /// support ATOPs. That way, this module ensures that the AXI
protocol remains in a defined state on
30 /// systems with mixed ATOP capabilities.
31 ///
32 /// ## Specification reminder
33 /// The AXI standard specifies that there may be no ordering
requirements between different atomic
34 /// bursts (i.e., a burst started by an AW with ATOP other
than 0) and none between atomic bursts

35 /// and non-atomic bursts [E2.1.4]. That is, **an atomic burst
may never have the same ID as any
36 /// other write or read burst that is in-flight at the same
time**.

27 /// Demultiplex one AXI4+ATOP slave port to multiple AXI4+ATOP
28 /// master ports.
29 ///
30 /// The AW and AR slave channels each have a `select` input to
31 /// determine to which master port the
32 /// current request is sent. The `select` can, for example,
33 /// be driven by an address decoding module
34 /// to map address ranges to different AXI slaves.
35 ///
36 /// ## Design overview
37 ///
38 /// [Block diagram](module.axi_demux.png "Block diagram")
39 ///
40 /// Beats on the W channel are routed by demultiplexer accord-
41 /// ing to the selection for the
42 /// corresponding AW beat. This relies on the AXI property
43 /// that W bursts must be sent in the same
44 /// order as AW beats and beats from different W bursts may
45 /// not be interleaved.
46 ///
47 /// Beats on the B and R channel are multiplexed from the mas-
48 /// ter ports to the slave port with
49 /// a round-robin arbitration tree.

APB

What this is. The APB peripheral bus.

Why it exists. Because not everything needs AXI. Configuration registers and slow peripherals are better served by a simple non-pipelined bus, and bridging AXI to APB is standard practice.

학부 복습 · EECS concepts. Simple bus protocols; address decoding; bridging between protocols.

석사 수준 · Practice note. APB's simplicity is its value: a peripheral with an APB interface is trivial to verify and to integrate. Consider it for any block whose bandwidth is not the point.

11 // APB Clock Domain Crossing
12 // Author: Manuel Eggimann <eggimann@iis.ee.ethz.ch>
13 // Description: A clock domain crossing module on an APB in-
  terface. The module uses gray-counting
14 // CDC FIFOs in both directions to synchronize source side
  with destination side.
15 // Parameters:
16 // - `LogDepth`: The FIFO crossing the clock domain has
  `2*LogDepth` entries
17 // - `req_t`: APB4 request struct. See macro definition in
  `include/typedef.svh`
18 // - `resp_t`: APB4 response struct. See macro defini-
  tion in `include/typedef.svh`

```

```

19 //
20 // Ports:
21 //
22 // - `src_pclk_i`: Source side clock input signal (1-bit).
23 // - `src_preset_ni`: Source side asynchronous active low reset
  signal (1-bit).
24 // - `src_req_i`: Source side APB4 request struct, bundles
  all APB4 signals from the master (req_t).
25 // - `src_resp_o`: Source side APB4 response struct, bundles
  all APB4 signals to the master (resp_t).
26 // - `dst_pclk_i`: Destination side clock input signal (1-
  bit).
27 // - `dst_preset_ni`: Destination side asynchronous active low
  reset signal (1-bit).
28 // - `dst_req_o`: Destination side APB4 request struct,
  bundles all APB4 signals to the slave (req_t).
29 // - `dst_resp_i`: Destination side APB4 response struct,
  bundles all APB4 signals from the slave (resp_t).
30 //
31 // This file also features the module `apb_cdc_intf`. The dif-
  ference is that instead of the
32 // request and response structs it uses a `APB` interfaces.
  The parameters have the same
33 // function, however are defined in `ALL_CAPS`.

1 //-----
2 // Title : APB Error Slave
3 //-----
4 // File : apb_err_slv.sv
5 // Author : Manuel Eggimann <meggimann@iis.ee.ethz.ch>
6 // Created : 05.12.2022
7 //-----
8 // Description :
9 // This module always responds with an error response on any
10 // request of its APB
11 // slave port. Use this module e.g. as the default port in a
12 // APB demultiplexer
13 // to handle illegal access. Following the recommendation of

```

```

the APB 2.0
12 // specification, the error response will only be asserted on
a valid
13 // transaction.

11 // APB Read-Write Registers
12 // Description: This module exposes a number of registers on
an APB interface.
13 // It responds to not mapped accesses with a
slave error.
14 // Some of the registers can be configured to be
read only.
15 // Parameters:
16 // - `NoApbRegs`: Number of registers.
17 // - `ApbAddrWidth`: Address width of `req_i.paddr`, is used
to generate internal address map.
18 // - `AddrOffset`: The address offset in bytes between the
registers. Is asserted to be a least
19 // `32'd4`, the reason is to prevent overlap in
the address map.
20 // Each register is mapped to a 4 byte wide
address range. When this parameter
21 // is bigger than `32'd4` there will be
holes in the address map and the module
22 // answers with `apb_pkg::RESP_SLVERR`. It
is recommended that this value is a
23 // power of 2, to prevent data alignment is-
sues on upstream buses.
24 // - `ApbDataWidth`: The data width of the APB4 bus, this
value can be up to `32'd32` (bit).
25 // - `RegDataWidth`: The data width of the registers, this
value has to be less or equal to
26 // `ApbDataWidth`. If it is less the re-
gister gets zero extended for reads and
27 // higher bits on writes get ignored.
28 // - `ReadOnly`: This flag can specify a read only re-
gister at the given register index of the
29 // array. When in the array the correspond-
ing bit is set, the `reg_init_i` signal
30 // at given index can be read out. Writes
are ignored if the flag is set.
31 // - `req_t`: APB4 request struct. See macro definition in
`include/typedef.svh`
32 // - `resp_t`: APB4 response struct. See macro defini-
tion in `include/typedef.svh`
33 //
34 // Ports:
35 //
36 // - `pclk_i`: Clock input signal (1-bit).
37 // - `preset_ni`: Asynchronous active low reset signal (1-
bit).
38 // - `req_i`: APB4 request struct, bundles all APB4
signals from the master (req_t).
39 // - `resp_o`: APB4 response struct, bundles all APB4
signals to the master (resp_t).
40 // - `base_addr_i`: Base address of this module, from here
the registers `0` are mapped, starting
41 // with index `0`. All subsequent register
with higher indices have their bases
42 // mapped with reg_index * `AddrOffset` from
this value (ApbAddrWidth-bit).
43 // - `reg_init_i`: Initialization value for each register,
when the register index is configured

```

```

44 // as `ReadOnly[reg_index] == 1'b1` this
value is passed through directly to
45 // the APB4 bus (Array size `NoApbRegs` *
RegDataWidth-bit).
46 // - `reg_q_o`: The current value of the register. If the
register at the array index is
47 // read only, the `reg_init_i` value is
passed through to the respective index
48 // (Array size `NoApbRegs` * RegDataWidth-
bit).
49 //
50 // This file also features the module `apb_regs_intf`. The
difference is that instead of the
51 // request and response structs it uses an `APB.Salve` inter-
face. The parameters have the same
52 // Function, however are defined in `ALL_CAPS`.

RISC-V 디버깅

What this is. The PULP RISC-V debug module.

Why it exists. Because **debug must work when nothing else does**, which is why it is a separate module with its own transport and clocking.

학부 복습 · EECS concepts. JTAG; debug transport modules; abstract commands; program buffers.

석사 수준 · Practice note. Compare with the OpenTitan debug module: both implement the same specification with different structural choices, which is a useful exercise in reading two implementations of one document.

25 // Design Name: OBI Wrapper for Debug Module
26 // (dm_top) //
27 // Project Name: CV32E40P //
28 // Language: SystemVeri- //
29 // log //
30 //
31 // Description: Wrapper for the Debug Module (dm_top) which
32 // gives it an //
33 // OBI (Open Bus Interface) compatible inter-
34 // faces so that it //
35 // can be integrated without further glue lo-
36 // gic (other than //
37 // tie offs in an OBI compliant sys-
38 // tem. //
39 //
40 // This wrapper is only intended for OBI com-
41 // pliant systems; //
42 //
43 // in other systems the existing dm_top can be
44 // used as before //
45 // and this wrapper can be ig-
46 // nored. //
47 //
48 // The OBI spec is available

CV32E40P RISC-V 코어

What this is. A 32-bit RISC-V core with PULP extensions, taped out in several projects.

Why it exists. Because it is the design under test in the step-and-compare methodology described in the verification chapters, and small enough to read completely.

학부 복습 · EECS concepts. Pipelining; hazard detection and forwarding; exception handling; CSR implementation.

석사 수준 · Practice note. Read the decode stage first, then the controller. Nearly all of a small core's complexity is in hazard and exception control, not in the datapath.

CV32E40P RVFI 트레이스

What this is. The RISC-V Formal Interface instrumentation for the core: retirement trace output.

Why it exists. Because model and RTL cannot be compared unless the RTL reports what it did. This module exposes, per retired instruction, the PC, the instruction word, register reads and writes, memory accesses and traps.

학부 복습 · EECS concepts. Observability; trace interfaces; instrumentation that does not alter behaviour.

석사 수준 · Practice note. If your project lacks an equivalent interface, **building one is the highest-value first task** a new modelling engineer can undertake: nothing else in the comparison flow can exist without it.

PicoRV32 -- 초소형 RISC-V

What this is. A very small RISC-V core, widely used in FPGA designs.

Why it exists. Because it shows how little is needed for a working processor. It trades cycles per instruction for area and is the clearest introduction to RISC-V RTL.

학부 복습 · EECS concepts. Multi-cycle versus pipelined execution; area–performance trade-offs; simple bus interfaces.

석사 수준 · Practice note. A good first core to read end to end. Understanding one complete core makes reading a complex one far easier.

SERV -- 비트직렬 RISC-V

What this is. A bit-serial RISC-V core — among the smallest in existence.

Why it exists. Because it demonstrates the extreme of the area–time trade. Processing one bit per cycle makes the datapath almost disappear, at 32× the cycle count.

학부 복습 · EECS concepts. Bit-serial arithmetic; area–time product; extreme resource constraint.

석사 수준 · Practice note. Worth reading as an existence proof: many datapaths can be serialised when area matters more than latency, and the technique is under-used.

when
133      bits 0 to 3 gets updated
134
135      During an external interrupt the exception code is set
to
136      7, since SERV only support timer interrupts
137
138      During an exception, the exception code is assigned to
indicate
139      if it was caused by an ebreak instruction (3),
140
141      ecall instruction (11), misaligned load (4), misaligned
store (6)
142      or misaligned jump (0)
143
144      The expressions below are derived from the following
truth table
145      irq => 0111 (timer=7)
146      e_op => x011 (ebreak=3, ecall=11)
147      mem => 01x0 (store=6, load=4)
148      ctrl => 0000 (jump=0)
149      */

172
173 generate
174  /*
175  Because SERV is 32-bit bit-serial we need a counter
than can count 0-31
176
177  to keep track of which bit we are currently processing.
o_cnt and cnt_r
178  are used together to create such a counter.
The top three bits (o_cnt) are implemented as a normal

```

counter, but

```

179      instead of the two LSB, cnt_r is a 4-bit shift register
which loops 0-3
180      When cnt_r[3] is 1, o_cnt will be increased.
181
182      The counting starts when the core is idle and the
i_rf_ready signal
183      comes in from the RF module by shifting in the
i_rf_ready bit as LSB of
184      the shift register. Counting is stopped by using
o_cnt_done to block the
185      bit that was supposed to be shifted into bit 0 of
cnt_r.
186
187      There are two benefit of doing the counter this way
188
189      1. We only need to check four bits instead of five when
we want to check
190      if the counter is at a certain value. For 4-LUT archi-
tectures this means
191      we only need one LUT instead of two for each comparis-
on.
192
193      2. We don't need a separate enable signal to turn on
and off the counter
194      between stages, which saves an extra FF and a unique
control signal. We
195      just need to check if cnt_r is not zero to see if the
counter is
196      currently running

형식검증된 AXI/Wishbone 브리지

What this is. A bridge between Wishbone and AXI, developed with formal verification throughout.

Why it exists. Because a bus bridge is where protocol violations are introduced, and because protocol conformance is exactly the kind of local, bounded property that formal methods settle completely.

학부 복습 · **EECS concepts.** Formal property verification; protocol assertions; induction and bounded model checking.

석사 수준 · **Practice note.** Read the assertions before the implementation. They are a precise, executable statement of the AXI rules and are more instructive than the protocol specification's prose.

1. ZipCPU_wb2axip/rtl/addrdecode.v (467 lines)

```

1 ///////////////////////////////////////////////////////////////////
2 //
3 // Filename:    rtl/addrdecode.v
4 // {{{
5 // Project:    WB2AXIPSP: bus bridges and other odds and ends
6 //
7 // Purpose:    Supports bus crossbars by answering the ques-
tion, which slave
8 //
9 // does the current address need to be routed to? Re-
quests are
10 // pipelined using valid!/stall handshaking. For those
familiar with
11 // AXI, READY!=STALL. The outgoing stream is identical to
the incoming
12 // one, save for the (new) o_decode field. This is a bit-
mask containing
13 // one bit for each slave that the request might be routed
to, and one
14 // extra bit to indicate no slaves matched.
15 //
16 // The keys to the operation of this module are found in
the two
17 // parameters, SLAVE_ADDR and SLAVE_MASK.
18 //
19 // SLAVE_ADDR specifies the address of the slave in ques-
tion. It's a large
20 // array, with one address (i.e. one set of AW
bits) for each
21 // potential slave address region.
22 //
23 // SLAVE_MASK specifies which of the bits in SLAVE_ADDR
need to match in
24 // order to route a request to a that slave.
25 //
26 // It's important to guarantee that no two slaves will
ever map to the

```

```

26 // same address, and likewise any given slave may only map to
a single
27 // address region.
28 //
29 // Incidentally, the algorithm forces all slaves to have
an address
30 // aligned with their memory size. Hence a 2GB memory
must have an
31 // address (range) of either 0-2GB, 2GB-4GB, 4GB-6GB,
etc. However, a
32 // second slave having only 8kB of memory may be placed at
0-8kB,
33 // 8-16kB, 16-24kB, etc. For logic minimization purposes, it
is often to
34 // the advantage of the bus compositor to minimize the
number of mask
35 // bits, and hence 8kB slaves may be aliased to many
places in memory.
36 // Bus composition and address assignment, however, are
both outside of
37 // the scope of the operation of this module.
38 //

38 // LGFIFO is the log based-two of the number of
39 // entries
40 // in the FIFO, log_2(fifo size)
41 // parameter LGFIFO = 3,
42 //
43 // WIDTH is the number of data bits in each
44 // entry
45 // parameter WIDTH = 16,
46 //
47 // NFF is the number of flip flops used to
48 // cross clock domains.
49 // 2 is a minimum. Some applications appreci-
50 // ate the better
51 // parameter NFF = 2,
52 //
53 // This core can either write on the positive
54 // edge of the clock
55 // or the negative edge. Set WRITE_ON_POSEDGE
56 // (the default)
57 // to write on the positive edge of the clock.
58 // parameter [0:0] WRITE_ON_POSEDGE = 1'b1,
59 //
60 // Many logic elements can read from memory
61 // asynchronously.
62 // This capability is sometimes known as "Dis-
63 // tributed RAM" or
64 // "LUT RAM". Doing so, however, burdens the
65 // timing of any
66 // logic to follow. By setting OPT_RE-
67 // GISTER_READS, we force
68 // all reads to be synchronous and not burdened by
69 // any logic.
70 // This tends to work with more hardware. If
71 // your hardware does
72 // support "Distributed RAM", then you may be
73 // able to spare a
74 // clock of latency by clearing this parameter.

```

1 ///////////////////////////////////////////////////////////////////
2 //
3 // Filename:      rtl/axi2axi3.v
4 // {{{
5 // Project:      WB2AXIPSP: bus bridges and other odds and ends
6 //
7 // Purpose:      Bridge from an AXI4 slave to an AXI3 master
8 //
9 // The goal here is to not lose bus resolution, capacity
or capability,
10 // while bridging from AXI4 to AXI3. The biggest problem
with such
11 // a bridge is that we'll need to break large requests
(AxLEN>15) up
12 // into smaller packets. After that, everything should
work as normal
13 // with only minor modifications for AxCACHE.
14 //
15 // Opportunity:
16 // The cost of this core is very much determined by the
number of ID's
17 // supported. It should be possible, with little extra
cost or effort,
18 // to reduce the ID space herein. This should be a topic
for future
19 // exploration.
20 //
21 // Status:
22 // This core is an unverified first draft. It has past
neither formal
23 // nor simulation testing. Therefore, it is almost cer-
tain to have bugs
24 // within it. Use it at your own risk.
25 //

6 //
7 // Purpose:    Convert from AXI to AXI-lite with no performance loss.
8 //
9 // Performance: The goal of this converter is to convert from AXI to AXI-lite
10 //              while still maintaining the one-clock per transaction speed
11 //              of AXI. It currently achieves this goal. The design needs very little
12 //              configuration to be useful, but you might wish to resize the FIFOs
13 //              within depending upon the length of your slave's data path. The current
14 //              FIFO length, LGFIFO=4, is sufficient to maintain full speed. If the
15 //              slave, however, can maintain full speed but requires a longer
16 //              processing cycle, then you may need longer FIFOs.
17 //
18 //              The AXI specification does require an additional 2 clocks per
19 //              transaction when using this core, so your latency will go up.
20 //
21 // Related:    There's a related axidoube.v core in the same repository as
22 //              well. That can be used to convert the AXI protocol to something
23 //              simpler (even simpler than AXI-lite), but it can also do so for multiple
24 //              downstream slaves at the same time.

PCIe 코어

What this is. PCIe interface logic: transaction layer, data link layer, DMA.

Why it exists. Because **PCIe is the dominant system interconnect**, and because its layering shows how ordering rules, credit flow control and replay interact.

학부 복습 · **EECS concepts.** Layered protocols; credit-based flow control; packet ordering rules; retry mechanisms.

석사 수준 · **Practice note.** PCIe ordering rules (posted, non-posted, completion) are a frequent source of subtle bugs. They are worth studying as a specification-reading exercise in their own right.

RVFI UVM 에이전트

What this is. A UVM agent that monitors the RVFI interface and checks its properties.

Why it exists. Because the trace must be captured and checked, not merely emitted. The agent turns retirement events into transactions a scoreboard can consume.

학부 복습 · EECS concepts. UVM agent structure (driver, monitor, sequencer); transaction-level modelling; assertions.

석사 수준 · Practice note. This is the bridge between the RTL's observability and the comparison logic. Studying it shows concretely how a verification environment is layered.

step-compare 테스트벤치

What this is. The testbench that steps a reference ISS and the RTL core together and compares architectural state after every retired instruction.

Why it exists. Because it is the operational definition of a bug in a CPU project: model and design disagree. It compares the PC, all 32 general-purpose registers and the CSRs.

학부 복습 · **EECS concepts.** Reference-model comparison; scoreboarding; masking of implementation-defined state.

석사 수준 · **Practice note.** Read the comments. One records that static register checks were disabled because bus stalls made them fail — a real engineering compromise between coverage and usability, documented in place. **That is what honest verification code looks like.**

Spike ISS -- 참조모델 본체

What this is. The core of the RISC-V reference simulator: decoder, execution, CSRs, MMU, and one small file per instruction.

Why it exists. Because it is the canonical example of how a reference model should be organised. Instruction semantics live in individual files; state access is hidden behind macros; the decoder is table-driven. Extensions are additive.

학부 복습 · **EECS concepts.** Instruction set semantics; interpreter design; privilege and virtual memory modelling.

석사 수준 · **Practice note.** Adopt this structure. A model that grows by adding files rather than by editing a growing switch statement remains maintainable after fifty extensions.

Berkeley SoftFloat

What this is. A bit-exact software implementation of IEEE 754 arithmetic.

Why it exists. Because host floating point cannot be used in a reference model. Rounding modes, exception flags, subnormals and NaN propagation must match the specification exactly, and they must not vary with the machine running the simulation.

학부 복습 · **EECS concepts.** IEEE 754 semantics; rounding modes; exception flags; subnormal handling.

석사 수준 · **Practice note.** If you are handed a floating-point block to model, the first question is whether the existing model uses host arithmetic. If it does, the model is machine-dependent and every correctness claim made with it is provisional.

RISC-V 형식 명세 (Sail)

What this is. The RISC-V architecture written in Sail, a specification language from which both prose and an executable emulator are generated.

Why it exists. Because it removes the gap between the document and the model. When the specification is executable, the reference implementation cannot drift from it.

학부 복습 · **EECS concepts.** Formal semantics; specification languages; generated implementations.

석사 수준 · **Practice note.** This is the strongest available answer to the independence problem described in the verification chapters: rather than hoping two readers interpret a document identically, make the document itself executable.
