## CV32E40P RISC-V 코어

**What this is.** A 32-bit RISC-V core with PULP extensions, taped out in several projects.

**Why it exists.** Because it is the design under test in the **step-and-compare methodology** described in the verification chapters, and small enough to read completely.

**학부 복습 · EECS concepts.** Pipelining; hazard detection and forwarding; exception handling; CSR implementation.

**석사 수준 · Practice note.** Read the decode stage first, then the controller. Nearly all of a small core's complexity is in hazard and exception control, not in the datapath.

226 end
227 end
228 /*
229 When a branch is taken in EX, if_valid_i is asserted because
230 the BRANCH is resolved also in
231 case of stalls. This is because the branch information is
232 stored in the IF stage (in the prefetcher)
233 when branch_i is asserted. We introduced here an apparently
234 unuseful special case for
235 the JUMPS for a cleaner and more robust HW: theoretically,
236 we don't need to save the instruction
237 after a taken branch in EX, thus we will not do it.
238 */

## CV32E40P RVFI 트레이스

**What this is.** The RISC-V Formal Interface instrumentation for the core: retirement trace output.

**Why it exists. Because model and RTL cannot be compared unless the RTL reports what it did.** This module exposes, per retired instruction, the PC, the instruction word, register reads and writes, memory accesses and traps.

**학부 복습 · EECS concepts.** Observability; trace interfaces; instrumentation that does not alter behaviour.

**석사 수준 · Practice note.** If your project lacks an equivalent interface, **building one is the highest-value first task** a new modelling engineer can undertake: nothing else in the comparison flow can exist without it.

## PicoRV32 -- 초소형 RISC-V

**What this is.** A very small RISC-V core, widely used in FPGA designs.

**Why it exists. Because it shows how little is needed for a working processor.** It trades cycles per instruction for area and is the clearest introduction to RISC-V RTL.

**학부 복습 · EECS concepts.** Multi-cycle versus pipelined execution; area–performance trade-offs; simple bus interfaces.

**석사 수준 · Practice note.** A good first core to read end to end. Understanding one complete core makes reading a complex one far easier.

## SERV -- 비트직렬 RISC-V

**What this is.** A bit-serial RISC-V core — among the smallest in existence.

**Why it exists. Because it demonstrates the extreme of the area–time trade.** Processing one bit per cycle makes the datapath almost disappear, at 32× the cycle count.

**학부 복습 · EECS concepts.** Bit-serial arithmetic; area–time product; extreme resource constraint.

**석사 수준 · Practice note.** Worth reading as an existence proof: many datapaths can be serialised when area matters more than latency, and the technique is under-used.

172
173  generate
174    /*
175    Because SERV is 32-bit bit-serial we need a counter
than can count 0-31
176
177    to keep track of which bit we are currently processing.
o_cnt and cnt_r
178    are used together to create such a counter.
The top three bits (o_cnt) are implemented as a normal

```

counter, but

```

179      instead of the two LSB, cnt_r is a 4-bit shift register
which loops 0-3
180      When cnt_r[3] is 1, o_cnt will be increased.
181
182      The counting starts when the core is idle and the
i_rf_ready signal
183      comes in from the RF module by shifting in the
i_rf_ready bit as LSB of
184      the shift register. Counting is stopped by using
o_cnt_done to block the
185      bit that was supposed to be shifted into bit 0 of
cnt_r.
186
187      There are two benefit of doing the counter this way
188
189      1. We only need to check four bits instead of five when
we want to check
190      if the counter is at a certain value. For 4-LUT archi-
tectures this means
191      we only need one LUT instead of two for each comparis-
on.
192
193      2. We don't need a separate enable signal to turn on
and off the counter
194      between stages, which saves an extra FF and a unique
control signal. We
195      just need to check if cnt_r is not zero to see if the
counter is
196      currently running
197      */

## 형식검증된 AXI/Wishbone 브리지

**What this is.** A bridge between Wishbone and AXI, developed with formal verification throughout.

**Why it exists.** Because a bus bridge is where protocol violations are introduced, and because protocol conformance is exactly the kind of local, bounded property that formal methods settle completely.

**학부 복습 · EECS concepts.** Formal property verification; protocol assertions; induction and bounded model checking.

**석사 수준 · Practice note.** Read the assertions before the implementation. They are a precise, executable statement of the AXI rules and are more instructive than the protocol specification's prose.

### 1. ZipCPU\_wb2axip/rtl/addrdecode.v (467 lines)

```

1 ///////////////////////////////////////////////////////////////////
2 //
3 // Filename:    rtl/addrdecode.v
4 // {{{
5 // Project:    WB2AXIPSP: bus bridges and other odds and ends
6 //
7 // Purpose:    Supports bus crossbars by answering the ques-
tion, which slave
8 //
9 // does the current address need to be routed to? Re-
quests are
10 // pipelined using valid!/stall handshaking. For those
familiar with
11 // AXI, READY!=STALL. The outgoing stream is identical to
the incoming
12 // one, save for the (new) o_decode field. This is a bit-
mask containing
13 // one bit for each slave that the request might be routed
to, and one
14 // extra bit to indicate no slaves matched.
15 //
16 // The keys to the operation of this module are found in
the two
17 // parameters, SLAVE_ADDR and SLAVE_MASK.
18 //
19 // SLAVE_ADDR specifies the address of the slave in ques-
tion. It's a large
20 // array, with one address (i.e. one set of AW
bits) for each
21 // potential slave address region.
22 //
23 // SLAVE_MASK specifies which of the bits in SLAVE_ADDR
need to match in
24 // order to route a request to a that slave.
25 //
26 // It's important to guarantee that no two slaves will
ever map to the

```

```

26 // same address, and likewise any given slave may only map to
a single
27 // address region.
28 //
29 // Incidentally, the algorithm forces all slaves to have
an address
30 // aligned with their memory size. Hence a 2GB memory
must have an
31 // address (range) of either 0-2GB, 2GB-4GB, 4GB-6GB,
etc. However, a
32 // second slave having only 8kB of memory may be placed at
0-8kB,
33 // 8-16kB, 16-24kB, etc. For logic minimization purposes, it
is often to
34 // the advantage of the bus compositor to minimize the
number of mask
35 // bits, and hence 8kB slaves may be aliased to many
places in memory.
36 // Bus composition and address assignment, however, are
both outside of
37 // the scope of the operation of this module.
38 //

```

1 ///////////////////////////////////////////////////////////////////
2 //
3 // Filename:      rtl/axi2axi3.v
4 // {{{
5 // Project:      WB2AXIPSP: bus bridges and other odds and ends
6 //
7 // Purpose:      Bridge from an AXI4 slave to an AXI3 master
8 //
9 // The goal here is to not lose bus resolution, capacity
or capability,
10 // while bridging from AXI4 to AXI3. The biggest problem
with such
11 // a bridge is that we'll need to break large requests
(AxLEN>15) up
12 // into smaller packets. After that, everything should
work as normal
13 // with only minor modifications for AxCACHE.
14 //
15 // Opportunity:
16 // The cost of this core is very much determined by the
number of ID's
17 // supported. It should be possible, with little extra
cost or effort,
18 // to reduce the ID space herein. This should be a topic
for future
19 // exploration.
20 //
21 // Status:
22 // This core is an unverified first draft. It has past
neither formal
23 // nor simulation testing. Therefore, it is almost cer-
tain to have bugs
24 // within it. Use it at your own risk.

4 // {{{
5 // Project:    WB2AXIPSP: bus bridges and other odds and ends
6 //
7 // Purpose:    Convert from AXI to AXI-lite with no performance loss.
8 //
9 // Performance: The goal of this converter is to convert from AXI to AXI-lite
10 //              while still maintaining the one-clock per transaction speed
11 //              of AXI. It currently achieves this goal. The design needs very little
12 //              configuration to be useful, but you might wish to resize the FIFOs
13 //              within depending upon the length of your slave's data path. The current
14 //              FIFO length, LGFIFO=4, is sufficient to maintain full speed. If the
15 //              slave, however, can maintain full speed but requires a longer
16 //              processing cycle, then you may need longer FIFOs.
17 //
18 //              The AXI specification does require an additional 2 clocks per
19 //              transaction when using this core, so your latency will go up.
20 //
21 // Related:    There's a related axidoube.v core in the same repository as
22 //              well. That can be used to convert the AXI protocol to something
23 //              simpler (even simpler than AXI-lite), but it can also do so for multiple
24 //              downstream slaves at the same time.
25 //

## PCIe 코어

**What this is.** PCIe interface logic: transaction layer, data link layer, DMA.

**Why it exists.** Because **PCIe is the dominant system interconnect**, and because its layering shows how ordering rules, credit flow control and replay interact.

학부 복습 · **EECS concepts.** Layered protocols; credit-based flow control; packet ordering rules; retry mechanisms.

석사 수준 · **Practice note.** PCIe ordering rules (posted, non-posted, completion) are a frequent source of subtle bugs. They are worth studying as a specification-reading exercise in their own right.

## RVFI UVM 에이전트

**What this is.** A UVM agent that monitors the RVFI interface and checks its properties.

**Why it exists. Because the trace must be captured and checked, not merely emitted.** The agent turns retirement events into transactions a scoreboard can consume.

**학부 복습 · EECS concepts.** UVM agent structure (driver, monitor, sequencer); transaction-level modelling; assertions.

**석사 수준 · Practice note.** This is the bridge between the RTL's observability and the comparison logic. Studying it shows concretely how a verification environment is layered.

## step-compare 테스트벤치

**What this is.** The testbench that steps a reference ISS and the RTL core together and compares architectural state after every retired instruction.

**Why it exists. Because it is the operational definition of a bug** in a CPU project: model and design disagree. It compares the PC, all 32 general-purpose registers and the CSRs.

학부 복습 · **EECS concepts.** Reference-model comparison; scoreboarding; masking of implementation-defined state.

석사 수준 · **Practice note.** Read the comments. One records that static register checks were disabled because bus stalls made them fail — a real engineering compromise between coverage and usability, documented in place. **That is what honest verification code looks like.**
